Executive Summary

Every four years, MORPC develops forecasts for how housing and employment will be distributed throughout Central Ohio, as this distribution is critical for understanding traffic flow. These forecasts are created using our *Land Use Allocation Model* and are a primary data set used in the Travel Demand Model, to inform and prioritize transportation infrastructure needs, looking out to a 30-year planning horizon.

Anticipating change 30 years into the future is an uncertain effort. There are macro-economic, environmental, geopolitical, and social factors that can have unanticipated impacts on how and where population and job changes will occur. MORPC employs multiple demographic and geospatial methods to develop a sound and reasonable forecast of growth using the best data available at the time. The core principle is to begin with large predictable projections and work down to more detailed less predictable ones, thus minimizing the amount of uncertainty in the projection methods. **Figure 1** summarizes the land use allocation process, as it feeds into the Travel Demand Model.

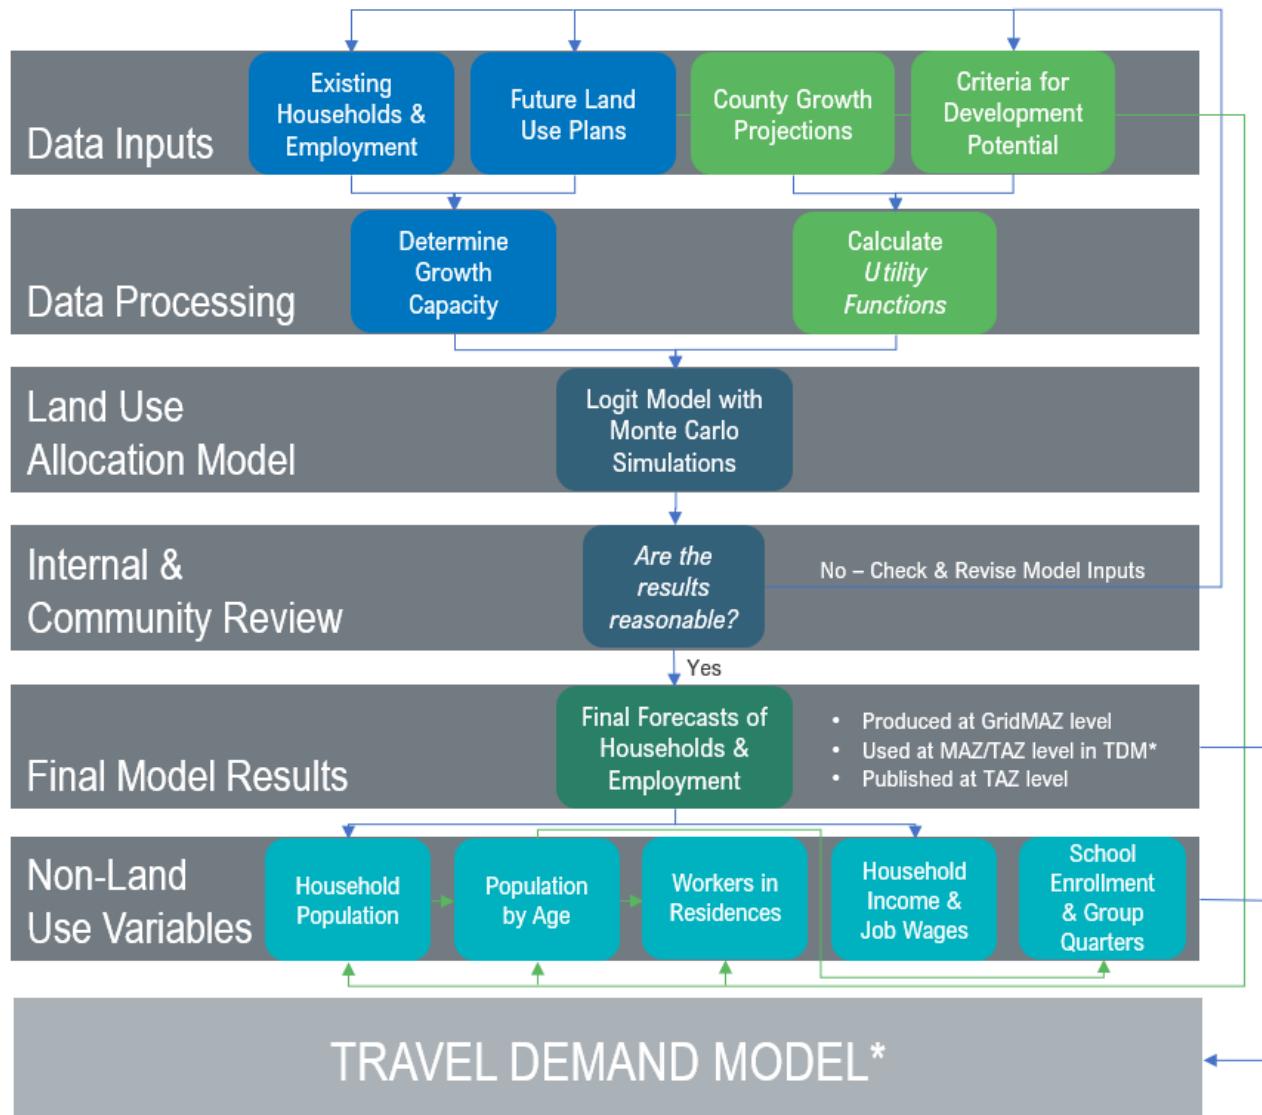

Figure 1. Land Use Allocation Model Flowchart

Geographies

MORPC's land use allocation model covers seven counties in central Ohio including Delaware, Fairfield, Franklin, Licking, Madison, Pickaway and Union. It is data driven and dependent on GIS and demographic data at small geographies we refer to as GridMAZ. The GridMAZ are an overlay of MORPC's Micro Analysis Zones (MAZ) and $\frac{1}{4}$ mile, 40 acres grids. Having the data at the GridMAZ geography for our seven-county area allows it to be easily summarized at various levels, with Traffic Analysis Zone (TAZ) being important for the travel demand model. TAZ level data for the base year 2018 and the horizon year 2050 are reported at the end of this appendix in **Table 17**.

Existing Conditions

Estimating future growth starts with understanding existing conditions, using various data sets to determine the locations of people and jobs throughout the 7-county region. The distribution of the population in the base year (2018) is estimated using administrative records (births, deaths, and migration), building permits issued after 2010 (the latest year of an official census), and U.S. Census Bureau American Community Survey estimates of average household size and rates of housing occupancy.

The distribution of jobs in the base year (2018) is estimated from Quarterly Census of Employment and Wages (QCEW) data, collected for the Bureau of Labor Statistics. New development activity (e.g. new facilities, relocations, and facility closures) not yet reflected in the QCEW is also considered in the 2018 employment estimates.

Land use types for every parcel within the 7-county region are standardized to MORPC's land use classification system to reflect conditions in the base year. This existing parcel level land use (see **Figure 4**) serves as a good reference tool for population and job assignments.

County Growth Control Totals

With a clear picture of where in the region people live and work currently, the next step is to predict how that will change and grow in the future. There is greater certainty in predicting future growth of larger populations than small ones, therefore MORPC's land use allocation model uses projections of future households and jobs within each county as the starting point for predicting where, specifically, growth is likely to occur.

A statistical model, using historic annual population data, back to year 1980, is used to predict annual population growth in central Ohio counties to the horizon year 2050. The model produces a most-likely set of population numbers, as well as a range of possible outcomes that reflect possible, but hard-to-predict changes that could impact the trajectory of population growth in the region. For MORPC's planning purposes, the median growth projections are used. From these projections of population growth, other 'county control totals' like future growth of households and jobs are estimated. County growth projections are listed in **Tables 1 – 6**.

Future Land Use

Community land use plans (or zoning, when a land use plan is not available) are collected from local jurisdictions throughout the 7-county region (see **Table 7**). The decisions made at the local level about the allowable and intended use of land in their communities is ultimately what determines where (and how much) growth of households and jobs can occur. The land use plans are converted into a standardized land use classification system, which reflects the type and density of future possible growth.

Many communities are using more flexible land use planning practices that allow for a mix of possible uses within a given area of land. *Mixed-use* designations vary widely in the type and density of different land uses (e.g. retail commercial and high-density residential, or office and light industrial). The designations were standardized into a typology of mixed-use categories that were incorporated into the land use allocation model (see **Table 8**).

Capacities

The land use allocation model then assigns the growth projected by the county control totals to very granular geographic areas (so called, *GridMAZ*). Each of these very small areas within a county is assigned with characteristics that allow the model to predict how much and what type of growth is most likely for that location. Paramount among these characteristics is the future land use type, as determined by local planning authorities, which is converted into MORPC's standard land use classification system. Each land use type defines both the type of future development and the total capacity (driven by locally determined densities) for growth of housing and/or jobs.

Criteria

Other criteria are also used to determine the attractiveness of a given location for future development—certain environmental constraints, access to infrastructure, and economic development incentives, for example, are identified as development criteria. The amount of ‘push’ or ‘pull’ a given criteria has on the development of new housing or job facilities is determined mathematically by how strongly those criteria attract or deter various types of development in the real world (see **Figures 11 & 12**).

Land Use Allocation Model

The land use allocation model is a *Logit Model*, which uses probabilities to distribute projected growth around a given county to those granular GridMAZ areas. The model uses all of the data inputs described to calculate 200 iterations of possible distributions of households and jobs in future years. The average of these 200 iterations of the model is the final forecast of future allocation of growth.

Non-Land Use Variables

The Land Use Allocation Model is used to predict future locations of households and jobs; however, the Travel Demand Model requires additional variables including population, households, group quarter population, labor force, median household income, income at place of work, school enrollment, and parking. Estimates of these variables in the future are each derived from the granular GridMAZ outputs of the Land Use Allocation Model—households and employment. Each variable is estimated using data sources and approaches specific to its characteristics and trends.

Land Use Allocation Model Results

The horizon year for this plan is 2050 and the base year is 2018. In addition, MORPC generates projections for 5-year increments. The projections are available for seven counties in central Ohio. Detailed information included in this Appendix is for the Columbus Metropolitan Planning Organization Planning Area (MPO) only, as displayed in **Figure 2**.

A web map displaying the forecast data at the Traffic Analysis Zone level can be found on the MORPC open data site: <https://public-morpc.hub.arcgis.com/>

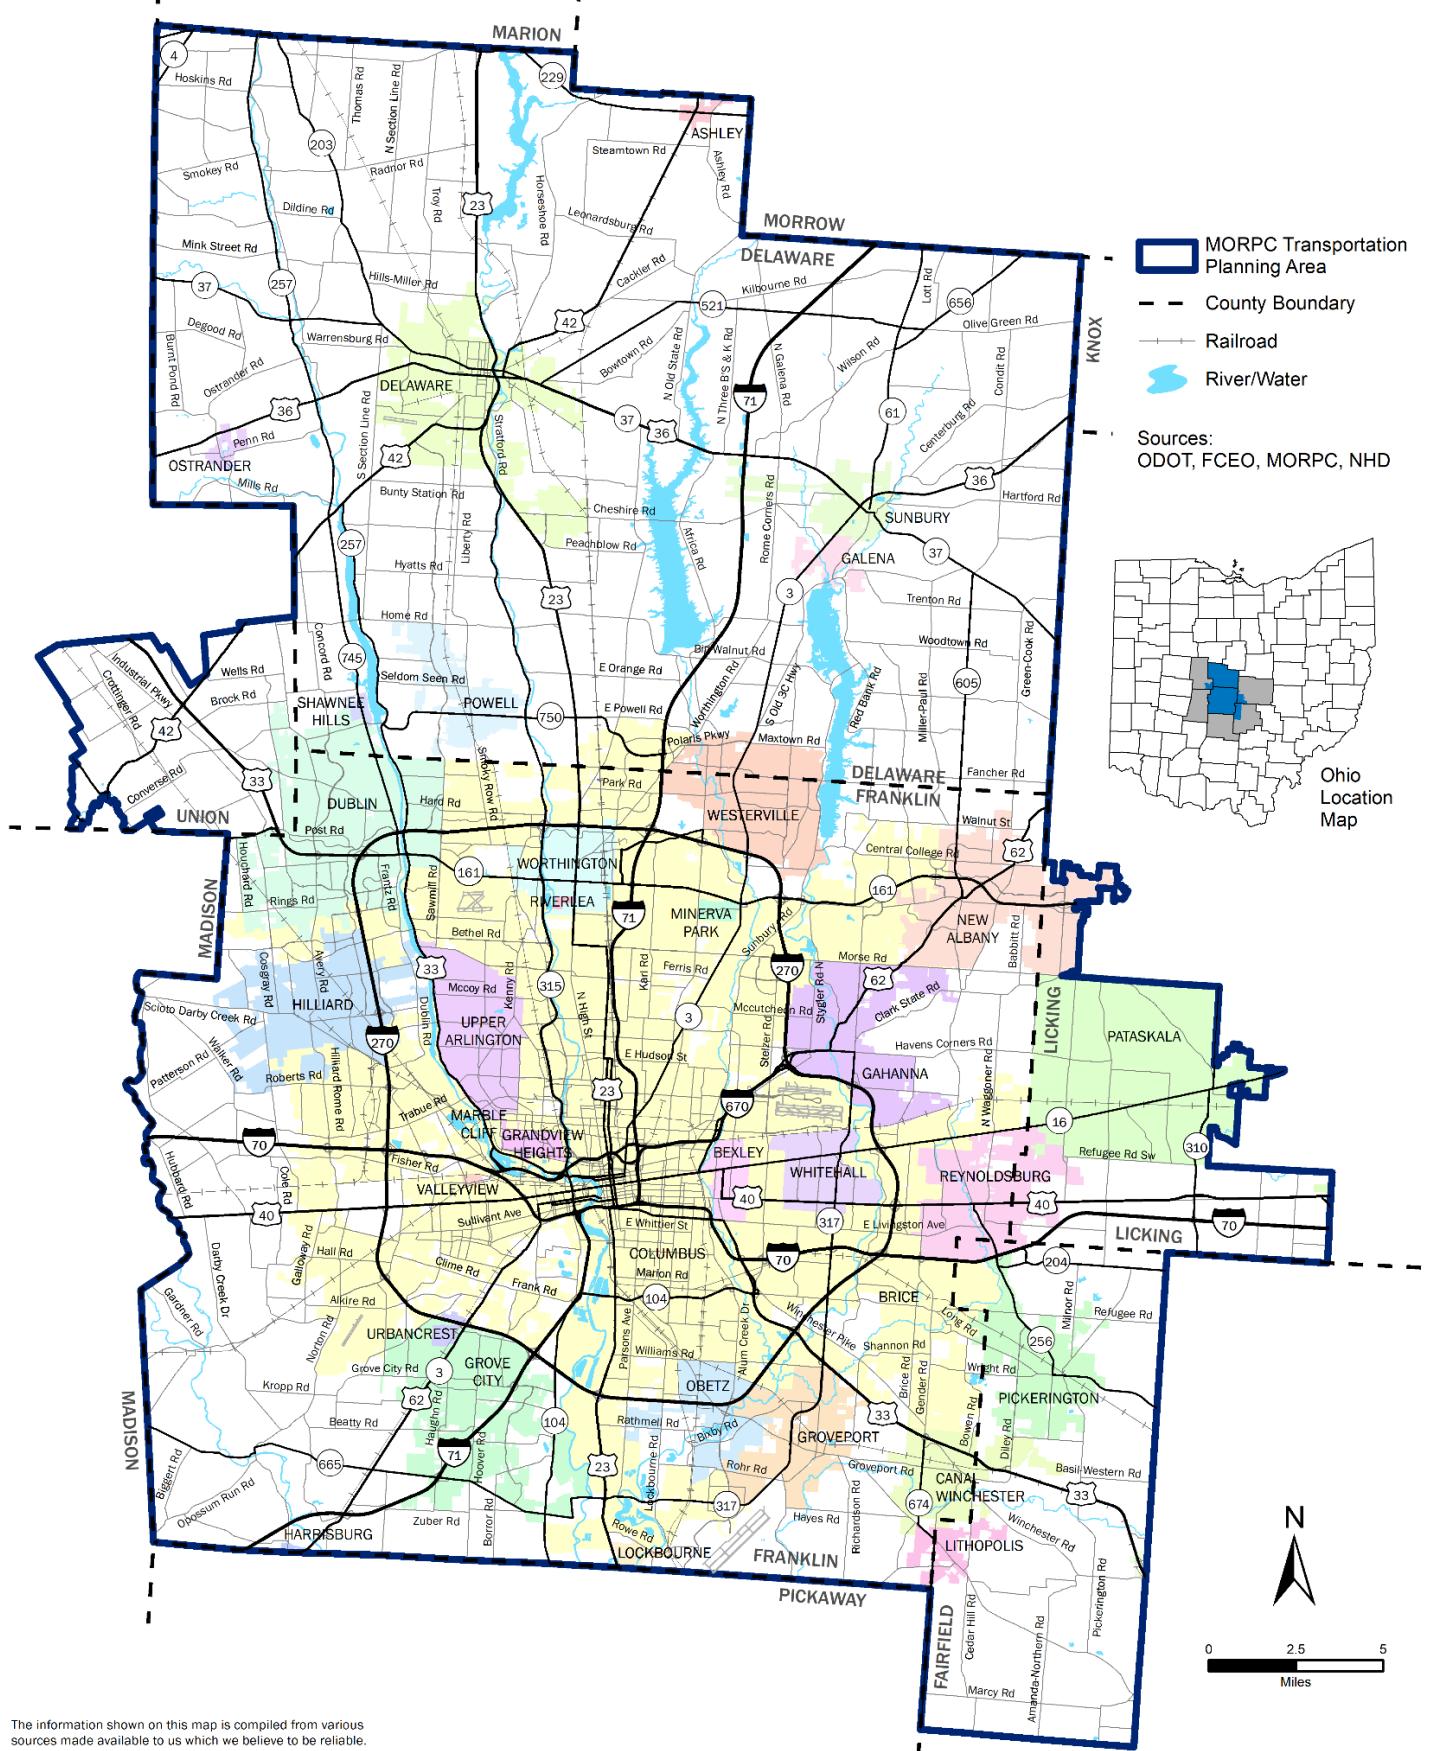

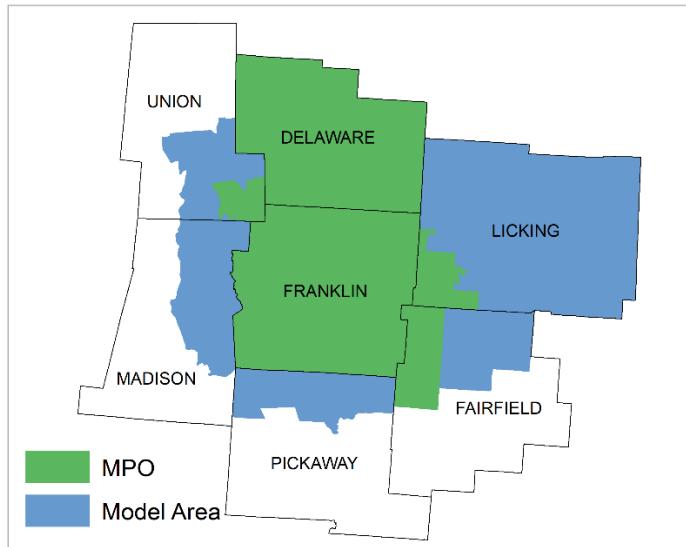

Figure 2. MORPC Transportation Planning Area

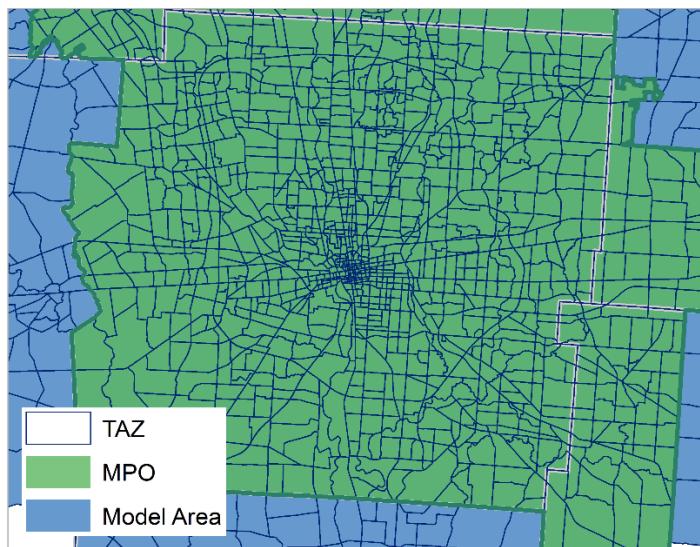

Geographies

Various geographies, within the seven-county area, are used as part of the land use model process, with county being the largest and parcel the smallest. (**Figure 3**) The MPO area is 2 full counties and portions of three others. (**Figure 2**) Control totals are created at the county level, land use at parcel level, and criteria assigned to GridMAZ. The MAZ are smaller areas within the TAZ and the GridMAZ are an intersection of the MAZ and a $\frac{1}{4}$ mile grid overlay. The Travel Demand Model consumes the data at the TAZ and MAZ level and these 2 geographies only exist within the Model Area. Outside of the Model Area the $\frac{1}{4}$ mile grids were merged to approximate TAZ sized areas. No MAZ exist outside the Model Area.

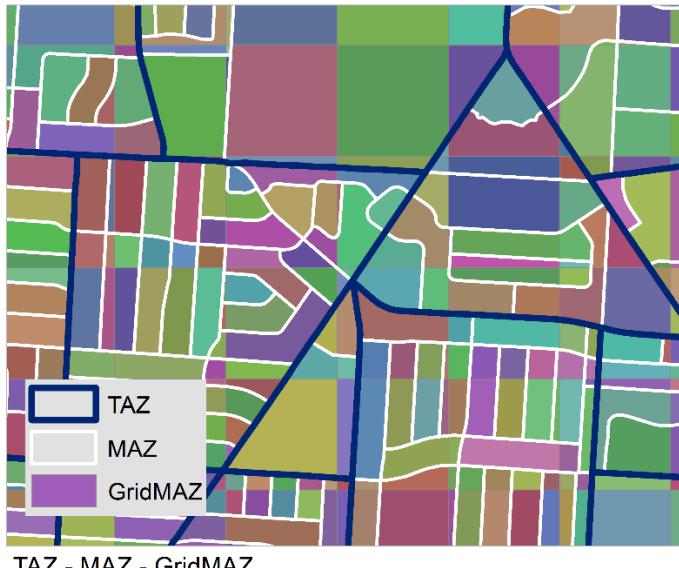

Note: The TAZ boundaries used for this MTP do not line up with previous years. Every 10 years the boundaries are adjusted, based on new development and model needs.

Traffic Analysis Zones (TAZ)

TAZ - MAZ - GridMAZ

Parcels (by land use type)

Figure 3. Geographies Used for Model

Existing Conditions

Land Use Parcels

MORPC collects parcel data from the auditor's office in all seven counties in the region to capture a snapshot of existing land uses. Because each has its own land use classification, standardized land use types were applied to create a uniform regional land use file. This land use data was then updated using current orthophotography, building permits and local knowledge to create the best available display of existing conditions. Land use changes occur frequently, and the documentation of those changes is not evenly reported in all counties. It is not possible to capture land use for an exact moment in time; however, the data are meant to capture land use reflecting 2018 conditions, approximately. The land use parcel layer was made available to the all local governments, via an editable web map for review, and edits were incorporated before finalizing this data input (**Figure 4**).

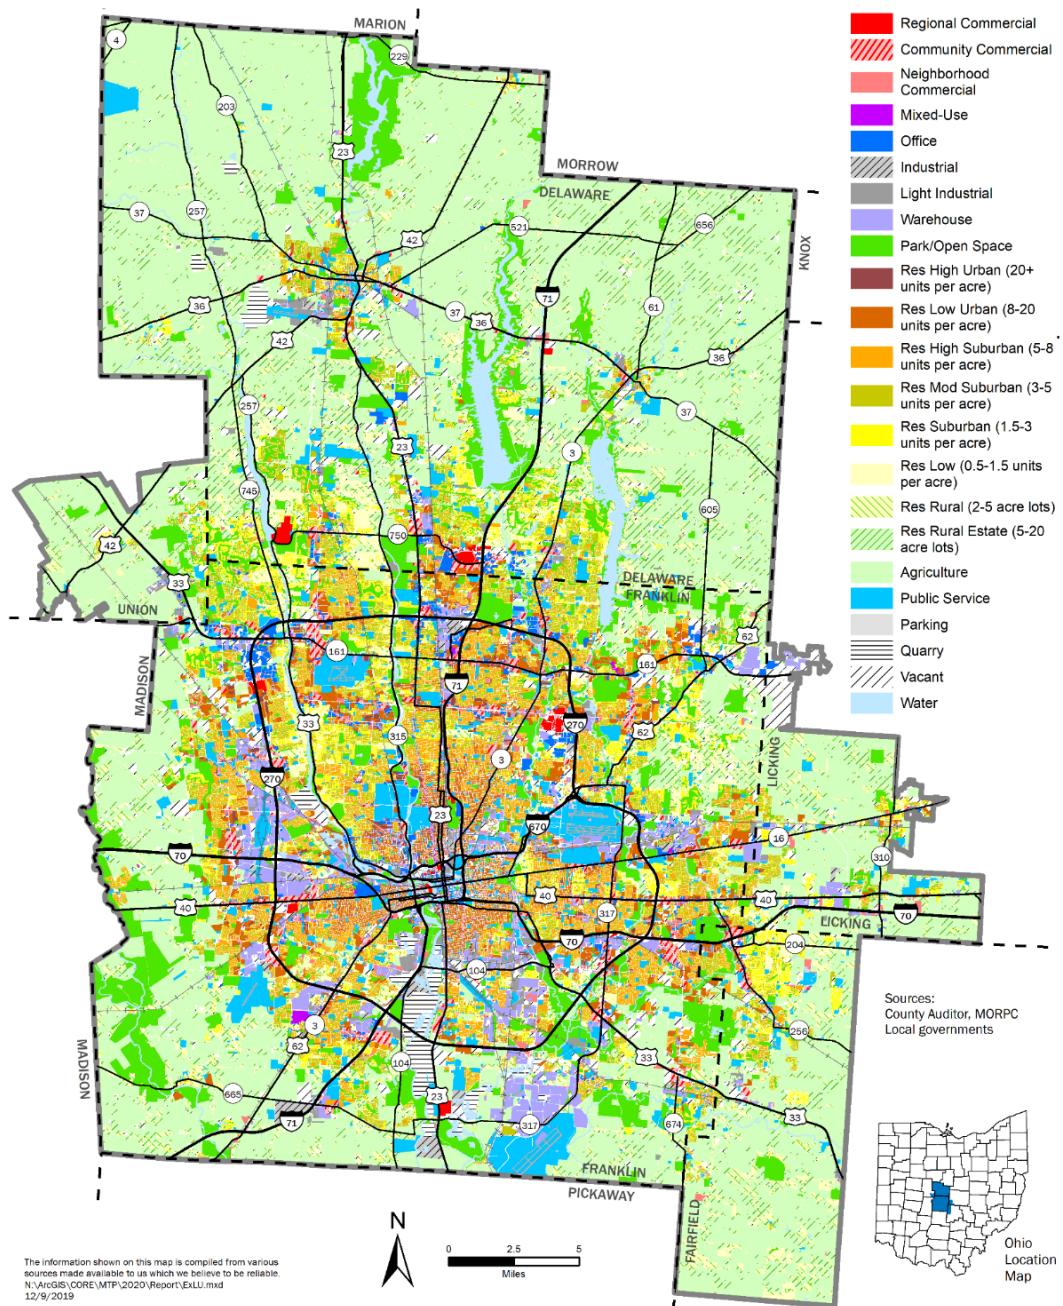

Figure 4. Existing Land Use by Parcels

Households & Population

The most recent counts of households and population for small geographic areas are from the 2010 decennial Census (Census Block geographies). The Land Use Allocation Model, however, requires a more current estimate of households and population to ensure the model is accounting for land that is already occupied. To ensure that more recent housing development is accounted for, MORPC residential building permit data was used (summarized by type in **Figure 5**). 2010 Census counts of housing units were combined¹ with housing units built since approximately the start of 2010 through the start of 2018. Estimates of housing units were then used to concurrently estimate households, household population, and total population in the base year².

Using the existing land use parcel data, residential land use types (eight types, with varying densities) were extracted and dissolved. The block and residential parcel layers were then combined, using the Block estimates (described above) to allocate households and population to more exact geographic locations by assigning them to residential land use areas according to the density in each location. From here the data was combined with and distributed to the smaller GridMAZ geographies, and the numbers were rounded using a *bucket rounding* approach.

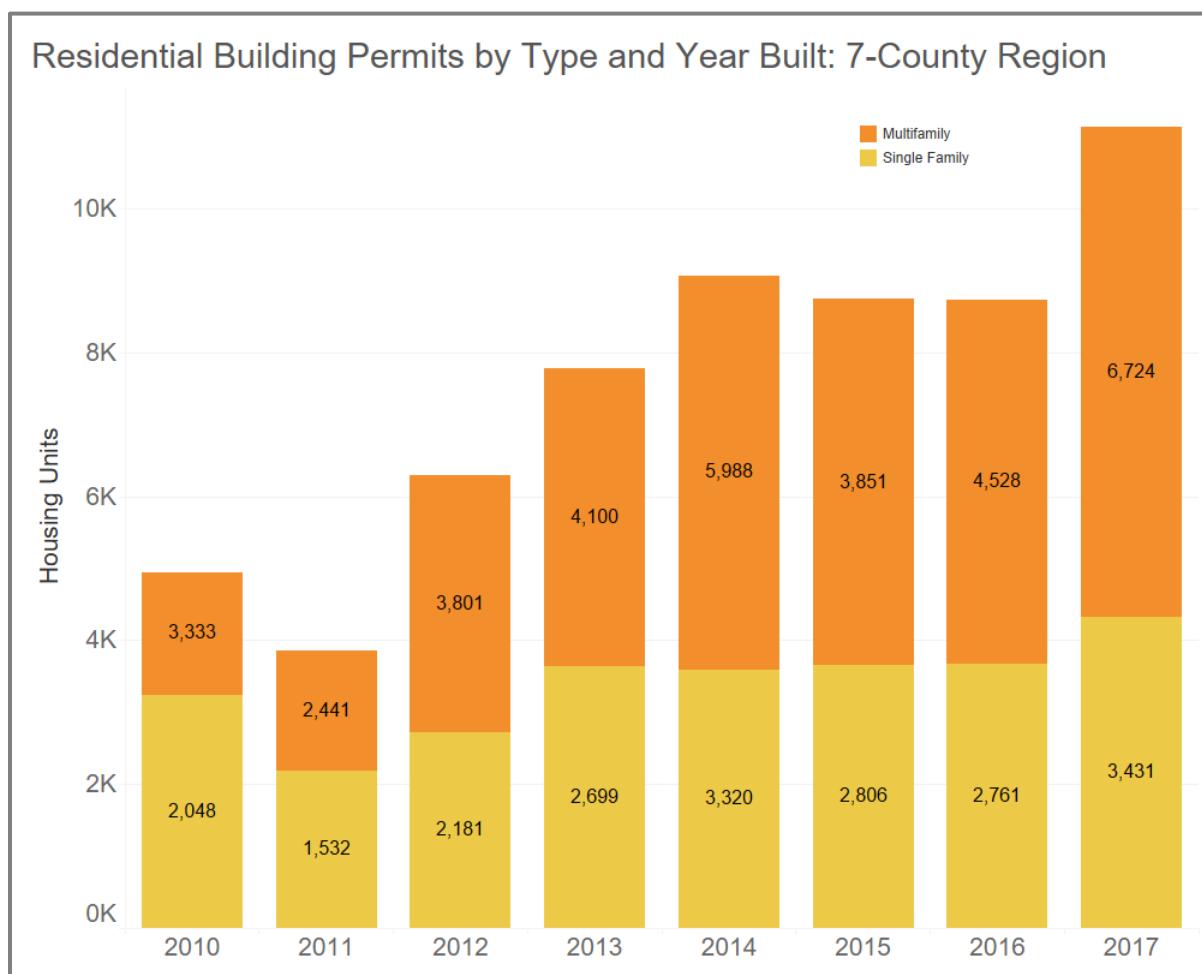

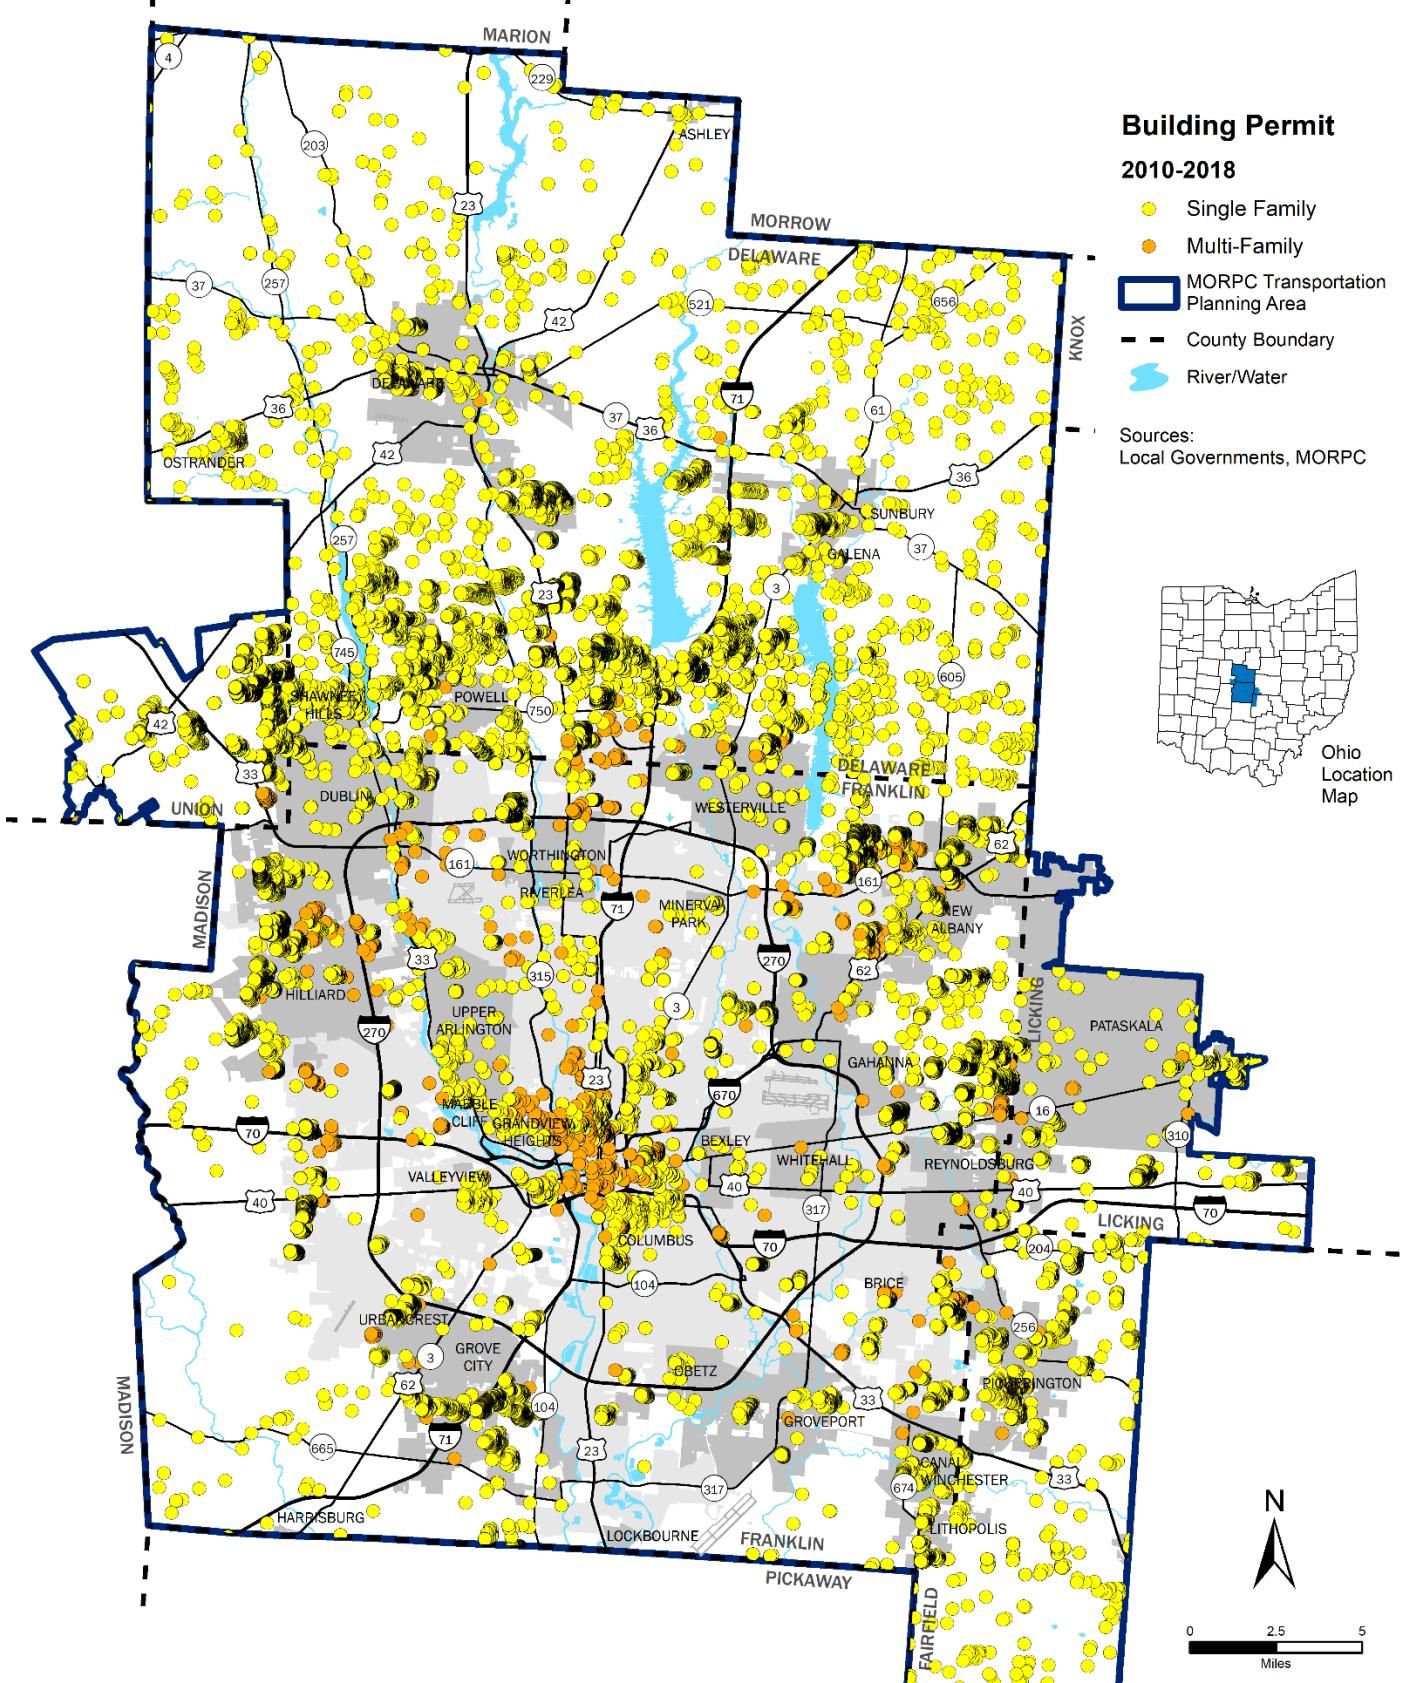

Figure 5. Residential Building Permits by Type in the 7-County Region

¹ In some instances, housing units that were counted in 2010 no longer exist. While it was not possible to account for every demolition, known instances (especially where larger apartment complexes were removed) were subtracted from estimates of existing housing units.

² Using 2018 county estimates and the 2012 – 2016 American Community Survey for household size and occupancy rates.

The information shown on this map is compiled from various sources made available to us which we believe to be reliable.

Figure 6. Residential Building Permits

Employment

The distribution of jobs in the base year (2018) is estimated using seasonally adjusted, establishment-level, employment data from the first quarter of 2018, provided by the Quarterly Census of Employment and Wages (QCEW—see **Figure 7**). The data is put through a series of processes to check and correct location accuracy, number of employees, and correct assignment of jobs to land-use based industry types.

Some of the establishment data was for a headquarter location (e.g. a corporate headquarters office, or a school district office) and all employees were counted at that location. In these cases, other facilities where the employees work were identified, and the ‘headquartered’ employees were distributed to their actual work locations.

New development activity (e.g. new facilities, relocations, and facility closures), identified from other sources, but not yet reflected in the QCEW data was also added to the 2018 employment estimates.

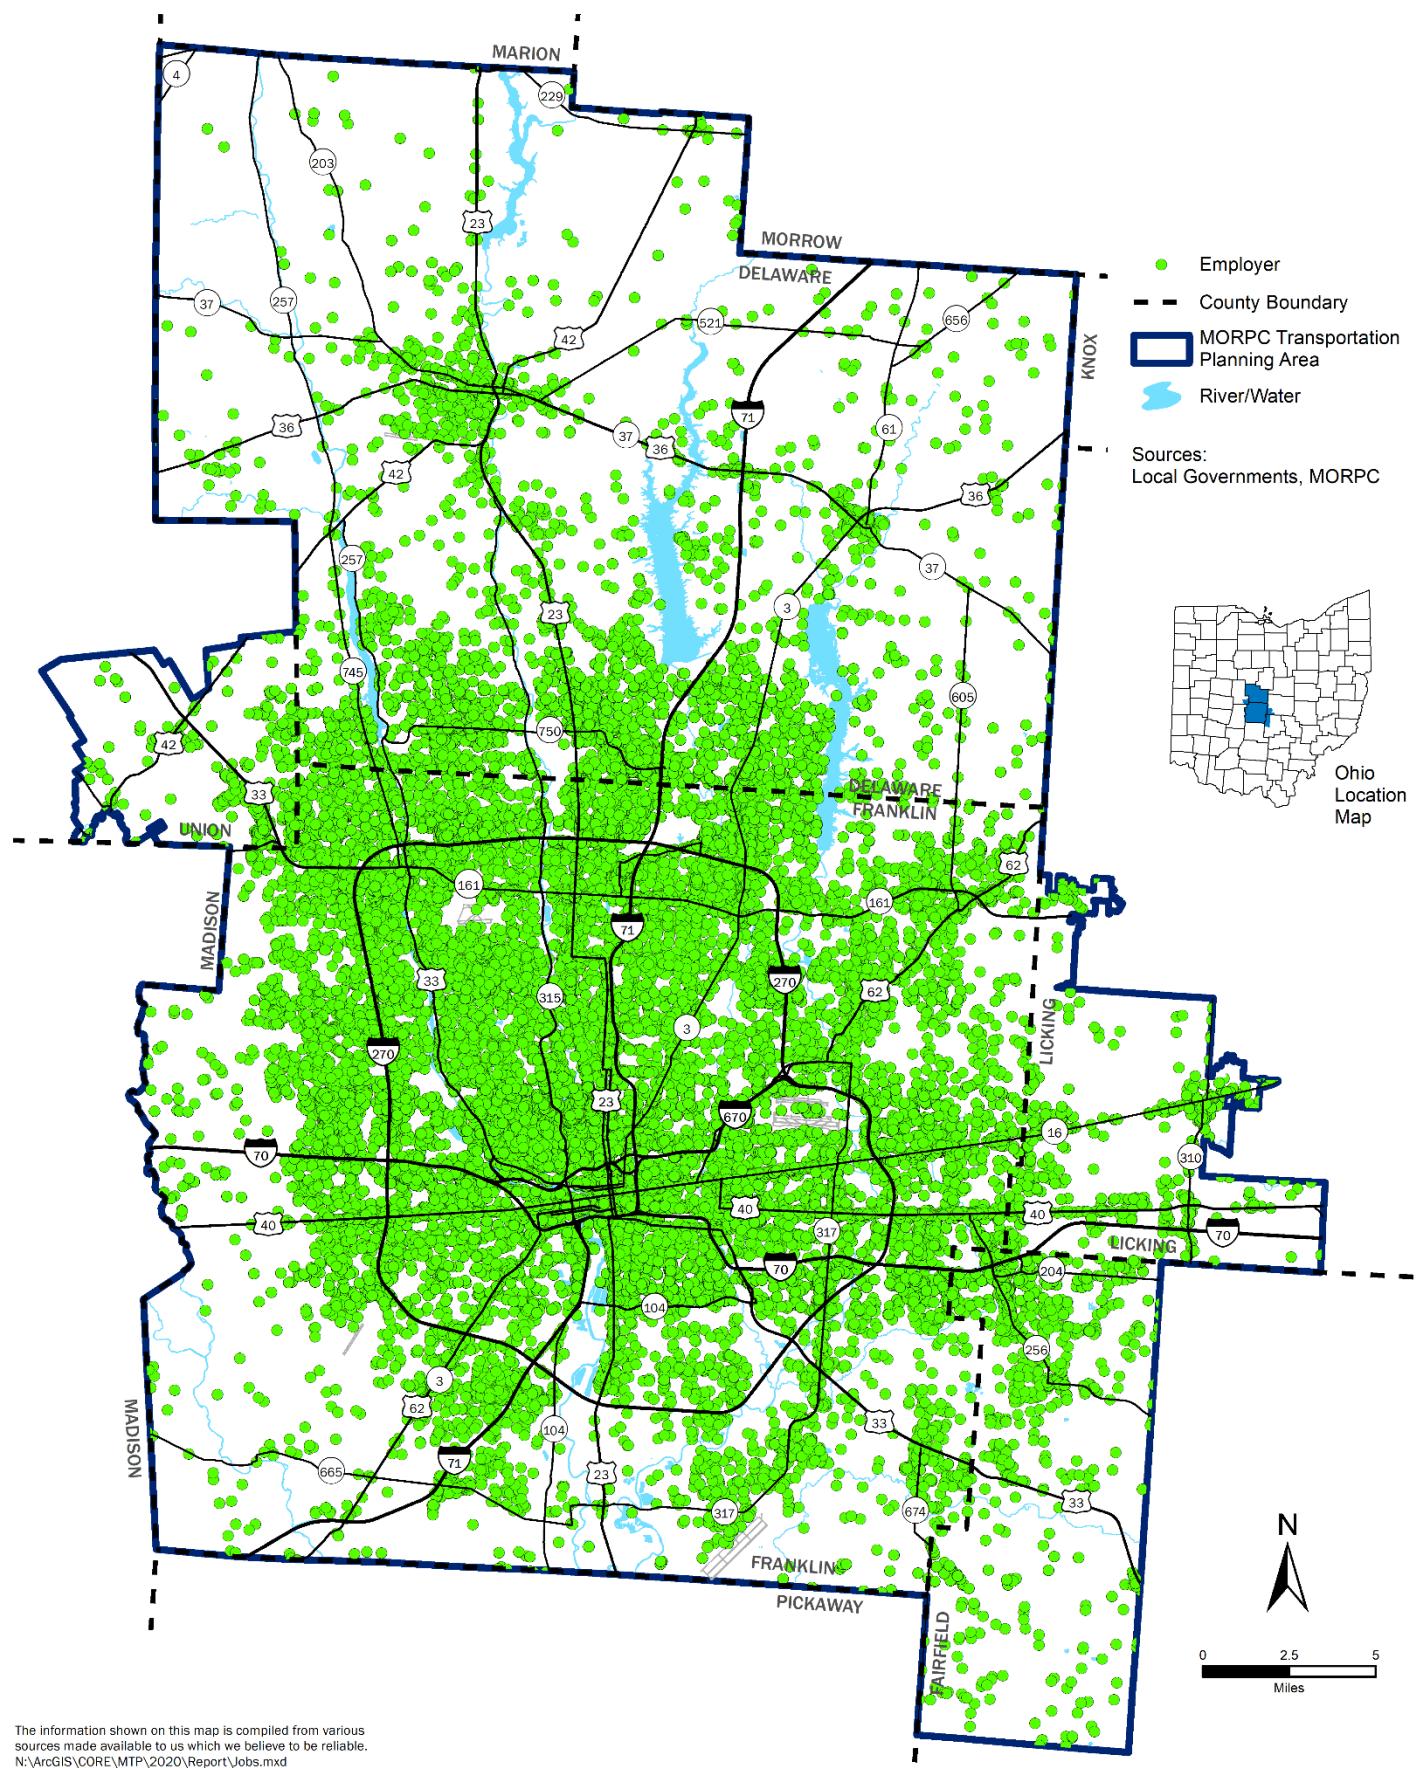

Employment data are associated with the North American Industry Classification System (NAICS). NAICS codes represent the industry of a business, but not necessarily the land use that is associated with a business establishment.

MORPC considers five broad, land use-based job categories—office, industrial, retail goods, retail services, and other. In most cases, NAICS codes (6-digit) can be adequately associated with one of the five MORPC job categories. Two exceptions to this were considered significant, and an approach was developed to correct for the inconsistency:

1. In some instances, a business may be in the industry of producing retail goods. Some of its establishments are for selling those goods, some for producing them, and others for distributing them—each different land uses—but they all share the same ‘retail’ NAICS code. Employment establishments with a retail NAICS code but located in industrial/warehouse areas were identified using existing land use and reclassified as *industrial* jobs.
2. Temporary workers (identified by NAICS codes) are counted in the QCEW in the staffing service locations and not in their actual work locations. These workers were redistributed to existing job locations according to temporary staffing demand in each of the five MORPC job types.

The employer locations are associated with land use types that host employment (commercial, office, industrial, etc.), summarized at the parcel level and then taken to the GridMAZ geographies in a process like the [household & population](#) data approach.

Employment numbers at the TAZ level were made available to local communities for review using an interactive web map. Due to confidentiality agreements, exact employment numbers at small geographies cannot be shared outside of MORPC. Numbers of employees were rounded and shown in ranges and growth between 2018 and 2050. The final employment data were summarized to the county level as the base year (2018) employment estimates for calculating future county employment projections.

The information shown on this map is compiled from various sources made available to us which we believe to be reliable.

Figure 7. Employer Locations

County Growth Control Totals

MORPC used an approach to develop sub-county forecasts that begins with projections of growth of households and jobs by industry type at the county level. **Figure 8** shows the process for establishing those growth control totals. The process requires multiple stages (the next dependent on the last) starting with projections for overall population growth.

County-level projections are available for the entire 15-county Central Ohio region, however detailed (small area) forecasts are available only for the seven Central Ohio counties that are wholly or partially within MORPC's travel demand modeling area.

The process begins with the overall trajectory of population growth at the county level using a statistical model that accounts for the cyclical pattern of population growth in the observed trend. This model was selected over the cohort-survival method because it is more sensitive to fluctuating migration patterns. The cohort-survival method typically uses a recent range of fertility rates, death rates, and migration rates by age groups, then assumes those rates will continue, thereby missing the ebb and flow of growth from migration.

Modeled future total population is then decomposed into key subgroups (population by age, population in households versus group quarters, and population in the labor force and employed workers), then translated into the number of households (based on household size and occupancy rates of housing units) and jobs (based on county-to-county commuting patterns) that would likely correspond with those additional people.

Future Land Use

The future land uses assigned to the parcels were sourced from planning documents approved by local planning authorities (e.g., comprehensive plans, area plans, zoning maps (see **Figure 9**). Communities were consulted to ensure the most current information was being used. **Table 7** is a list of the plans referenced. As with the existing land use, the standardized land use classification was applied to the future plans to create a single regional future land use dataset. Communities were provided the opportunity to review and comment on the future land use via an interactive editable web map, and necessary edits were made.

Note: If a land use plan did not exist the local zoning was used.

Local governments were provided an interactive web map to review and edit the land use we assigned.

Review by local governments or proposed development may contradict the land use plan

Mixed-Use

Many communities are increasingly calling for mixed-use development in their plans, particularly in areas targeted for redevelopment. This approach gives parameter and supports a mix of compatible land uses in the future while recognizing that the specific mix of uses may not be known until the time of development. In order to establish quantifiable capacities for growth within all mixed-use designations, they were converted into standard types, each with their own allowance for capacity. This required coordination with the local communities and an agreement on approximate densities and proportions of use types. **Figure 10** shows the amount of mixed-use land in the latest comprehensive plans. **Table 8** summarizes the MORPC land use equivalents assigned to each of the mixed-use types identified in community land use plans.

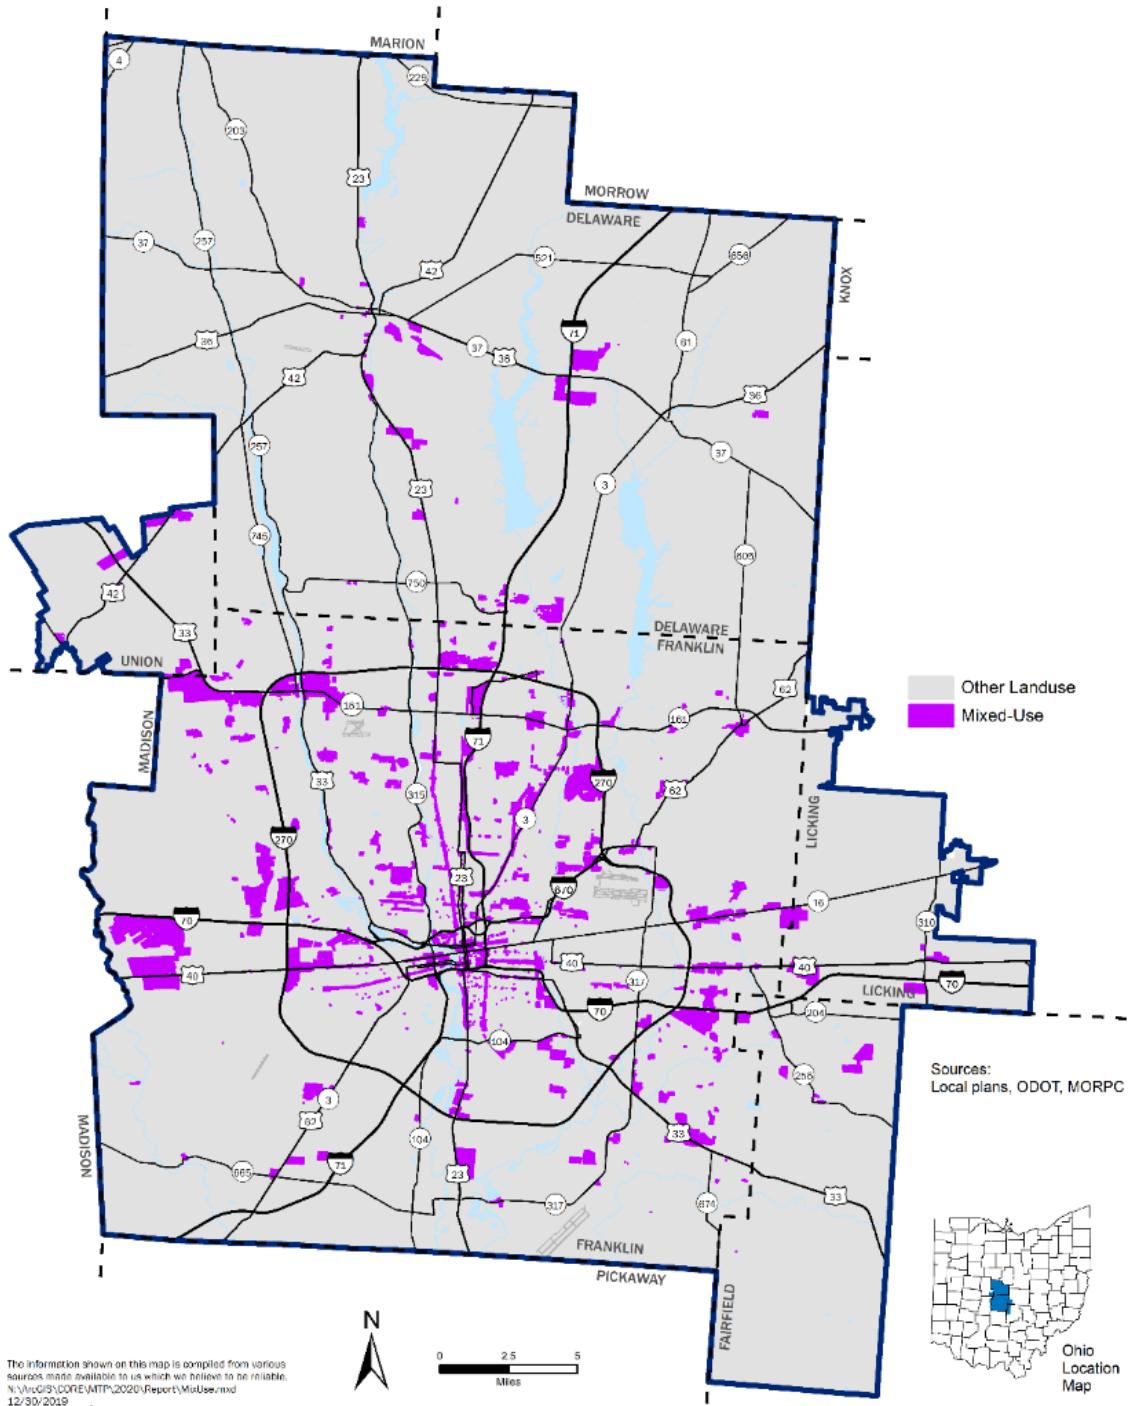

Figure 10. Future Mixed-Use Areas

Capacities

The capacity of each GridMAZ, that is, the maximum number of households or jobs it could theoretically hold, is dependent upon the expected land use. Within MORPC's standardized land use classifications, each land use type has a maximum density of houses for residential uses and employment for non-residential uses.

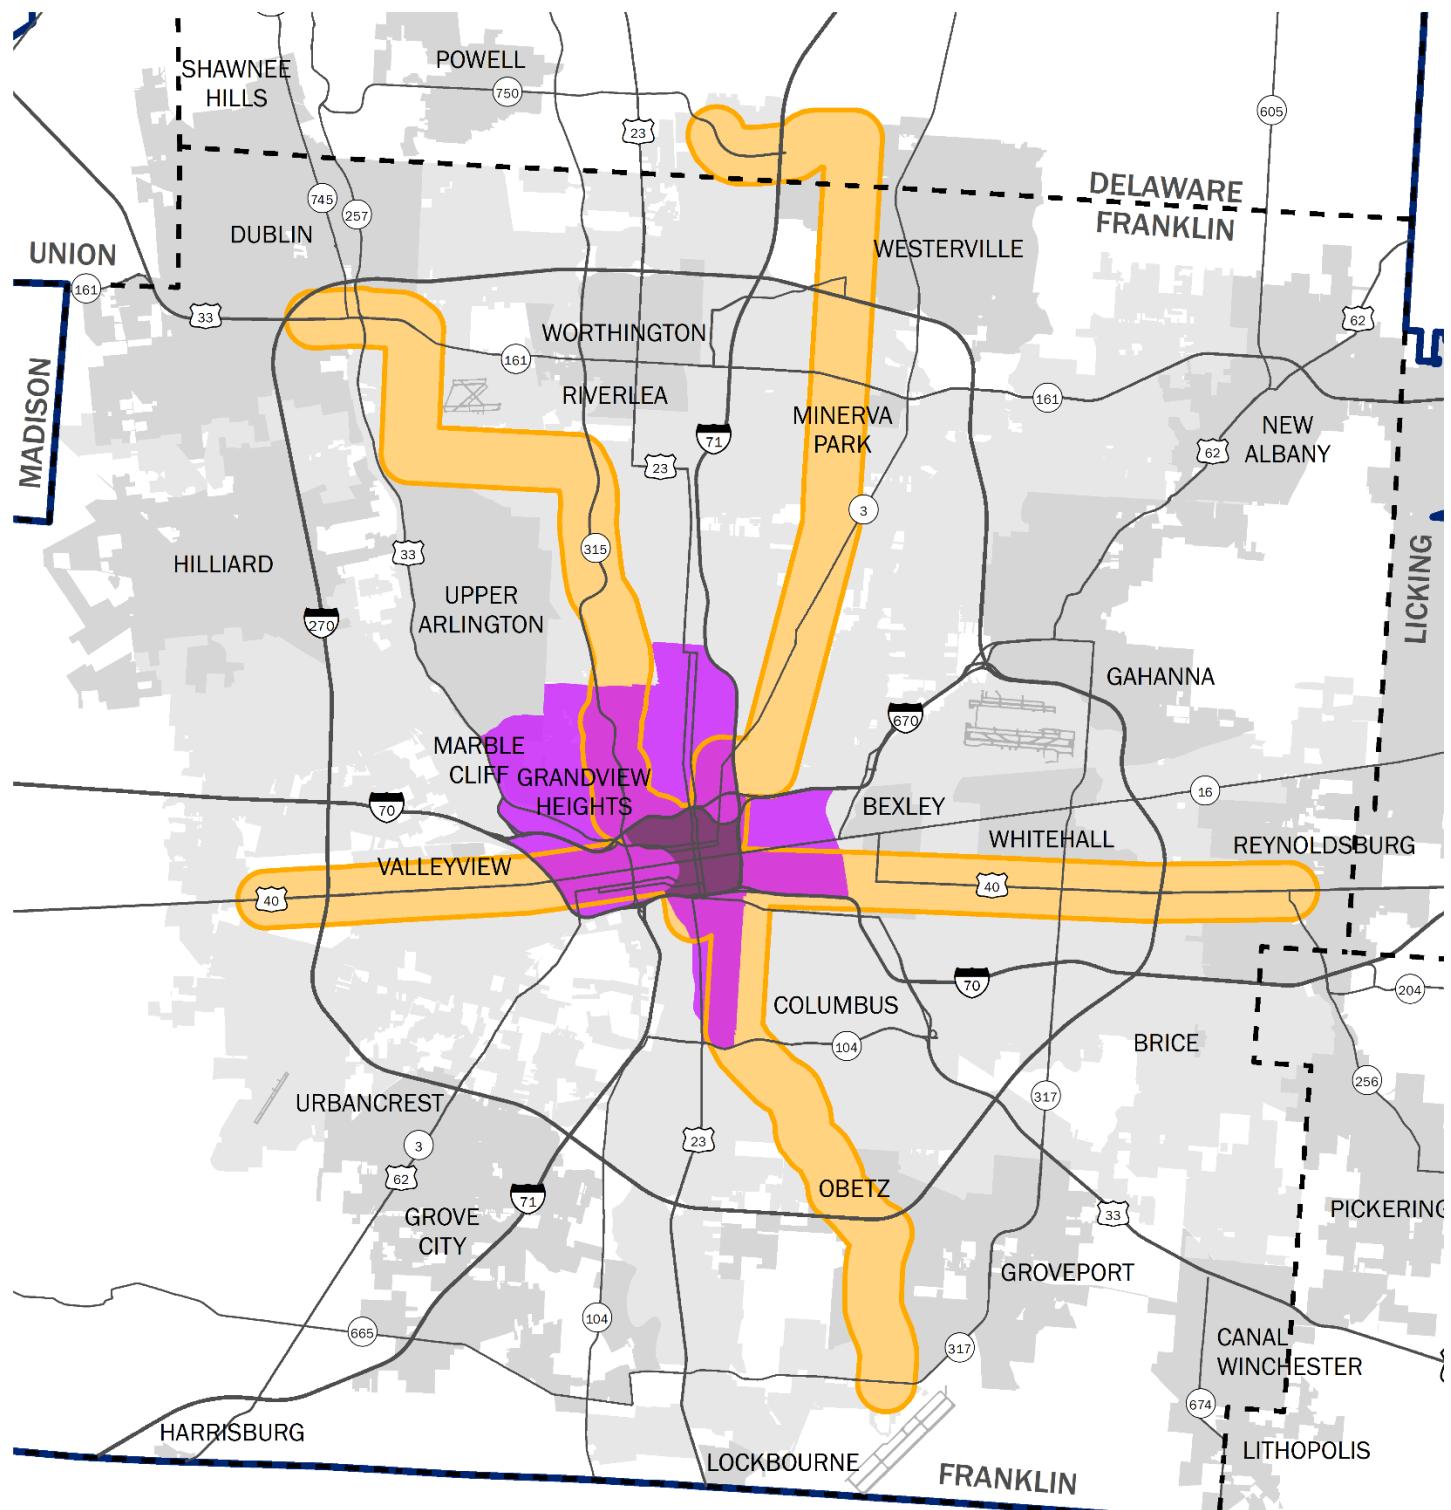

The typology is divided into basic land use types including agriculture, office, commercial, industrial, residential, open space, and institutional uses. Each type is then subdivided based on scale and density. For example, commercial uses are further characterized as neighborhood, community or regional. Industrial is divided between industry (manufacturing) and warehouses. Residential uses are characterized based on density of housing units. Finally, institutional uses include a plethora of uses ranging from religious to correctional facilities. Open space uses include parks, cemeteries, and golf courses.

Table 9 is a list of the land use types and the capacities for growth associated with each. An addition from previous years is the expansion of the *mixed-use* land use types discussed above. The mixed-use capacities and descriptions are listed in **Table 10**.

In addition to expanding future land use capacities to include a standardized typology of mixed-use classifications assigned by communities, two other factors were considered that were not included in previous years.

First, a review of existing population and household data revealed that there is currently a wide range of possible densities associated with the *High Urban Residential* land use code. While this code accurately describes existing locations as having densities of 20 units per acre or more, the upper limit for growth varies, and is found to be strongly tied to geography. Most high-density urban residential areas within the downtown area and some immediate surrounding neighborhoods were found to have densities approaching 160 units per acre. Most high-density urban residential areas in neighborhoods just beyond the downtown area were found to have densities approaching 80 units per acre. Finally, most high-density urban residential areas beyond the adjacent neighborhoods were found to have densities approaching 40 units per acre. As a result, the High Urban Residential code was subdivided into three zones with the appropriate corresponding densities (**Figure 11**)

The second adjustment to capacities is based on the *Insight2050 Corridor Concepts* study. *Corridor Concepts* determined that the five corridors could be reasonably expected to accommodate 55% of future residential growth and 60% of future job growth. A test was done to calculate, based on current community land use plans, whether there would theoretically be enough capacity to allow for the share of growth suggested in *Corridor Concepts*. That calculation revealed that, while there is currently enough capacity to support 60% of job growth within the corridors, there is not sufficient capacity to support 55% of residential growth based on current land use plans. If density allowances in the corridors were increased by 30%, there would be sufficient land to support this share of residential growth. In order to ensure the model could support the possibility of a coordinated regional effort to develop the five corridors, a multiplier was applied to the capacity in all residential land use types (including mixed-use types containing residential). The multiplier – 1.3—was based on the calculated residential capacity shortage described above.

The information shown on this map is compiled from various sources made available to us which we believe to be reliable.

Criteria

A set of criteria that influence where a developer chooses a project site were developed in 2008 with input from the private development community. A summary of these criteria is shown in **Figure 12**. Criteria include environmental constraints, access to infrastructure, and economic development incentives (maps shown in **Figures 14 – 19**).

The criteria were applied to each GridMAZ through GIS analysis, which allowed the model to quantitatively measure the likelihood of development based on the presence or absence of all of the factors that would either attract or deter development.

In previous years, the weights (or, numbers that the model uses to calculate the relative importance of each criteria) were determined based on qualitative feedback from a group of private development community members. For this MTP, a data-driven approach was used instead. With a method called *maximum likelihood estimation*, data were used to calculate the relationships between the model criteria and actual development outcomes. The result of the calculations are so-called *beta coefficients*, which are then used as the weights in the model that act as a measure of relative importance of each criterion. The [Land Use Allocation Model](#) section provides more information about how these coefficients were used in the model.

One exception to this approach was created by the need to incorporate the future impact of the *Corridor Concepts* study as a model criterion. *Corridor Concepts* provides guidance for cross-jurisdictional, coordinated efforts to encourage focused growth paired with high-capacity transit along five corridors (see **Figure 11** for corridors). To account for the likelihood of increased attractiveness of development resulting from high-capacity transit along these corridors, a criterion called *high-capacity transit* was added to the model. Since there is no existing data to measure the relationship between high-capacity transit and development in the region, a weight was selected to represent this relationship by testing a series of weight values and calibrating the values by studying the impact on the model results when different weights were used.

Factors that would make a site more attractive for residential development differ from factors that would attract different types of non-residential development. Based on this knowledge about development activity, weights were calculated independently for residential development (allocation of households), and non-residential development (allocation of jobs in each of the five MORPC industry categories—office, industrial, retail goods, retail services, and other).

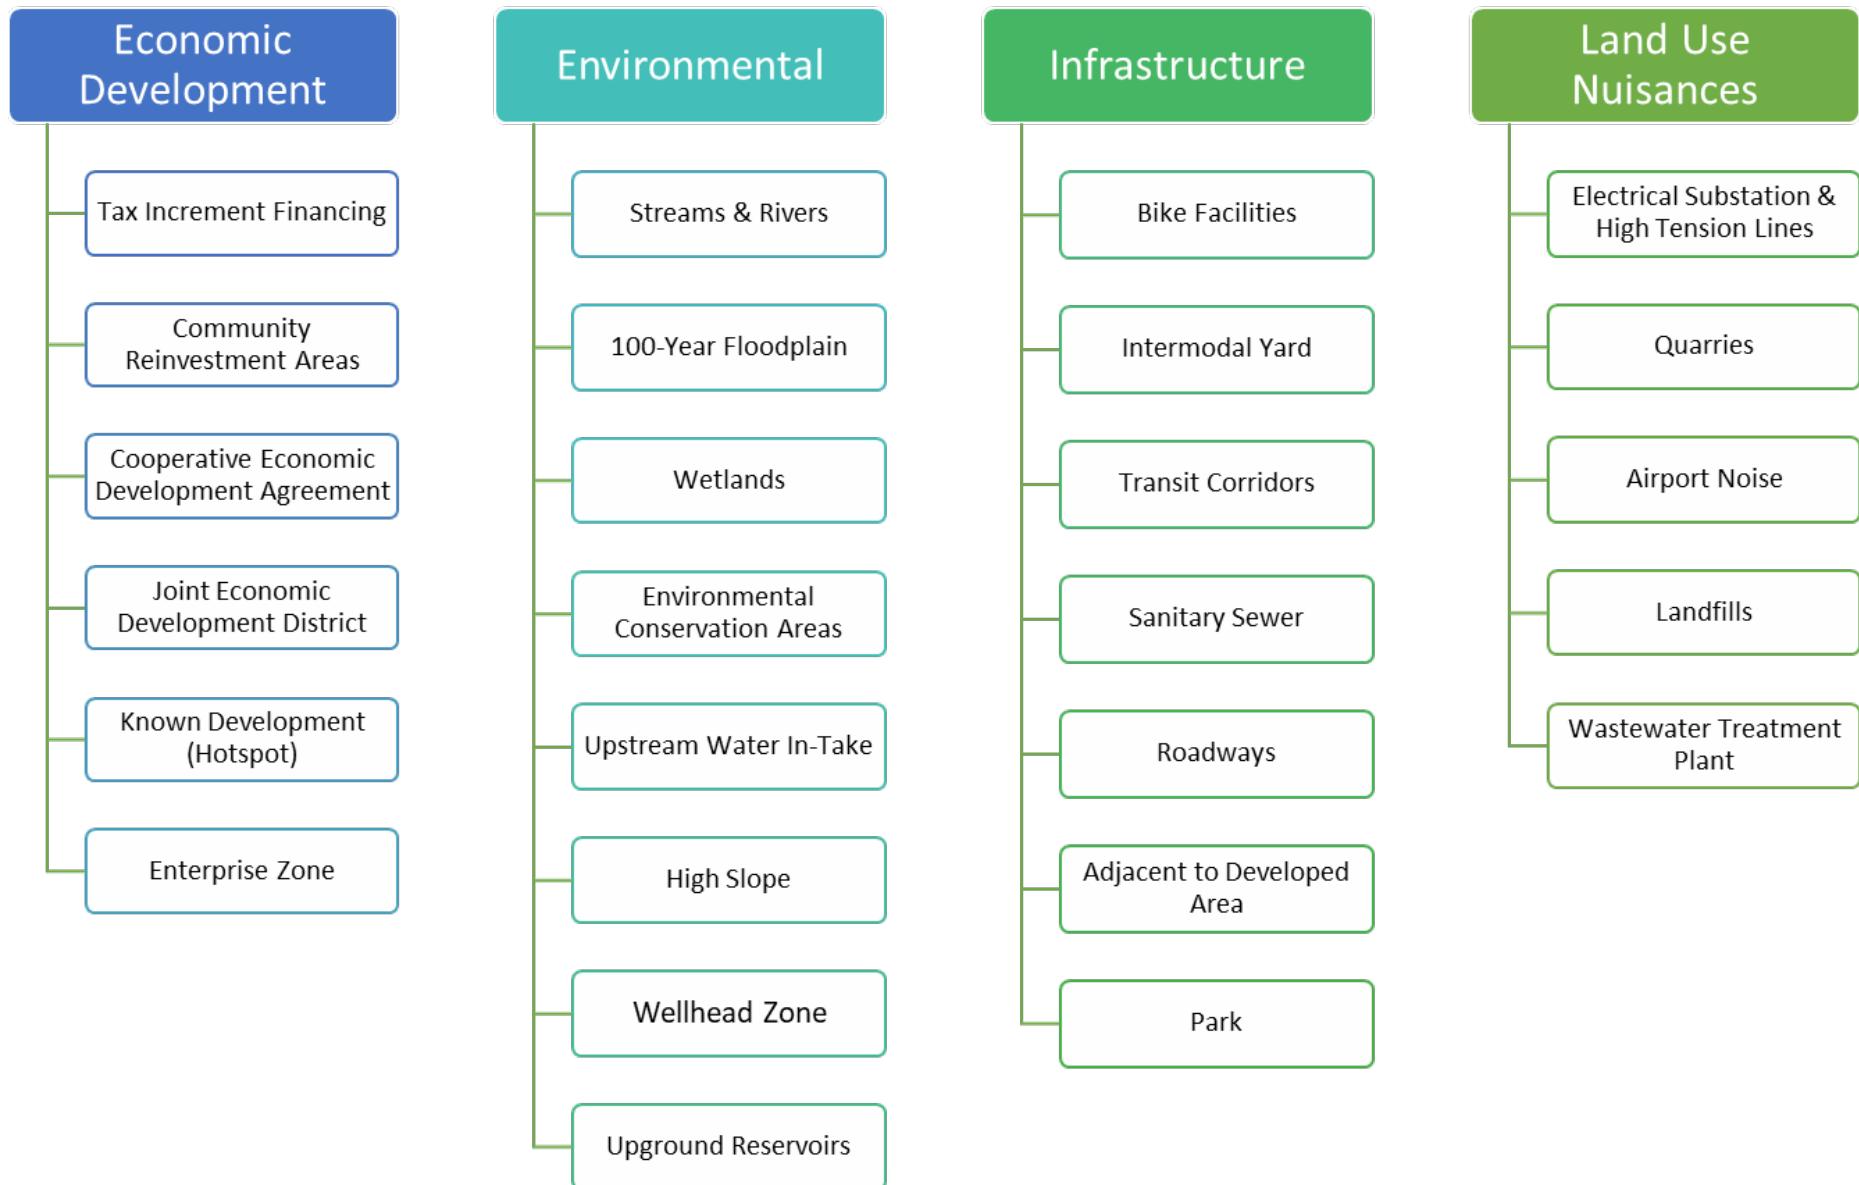

Figure 12. Land Use Allocation Criteria Categories

Land Use Model Criteria (MTP 2020)

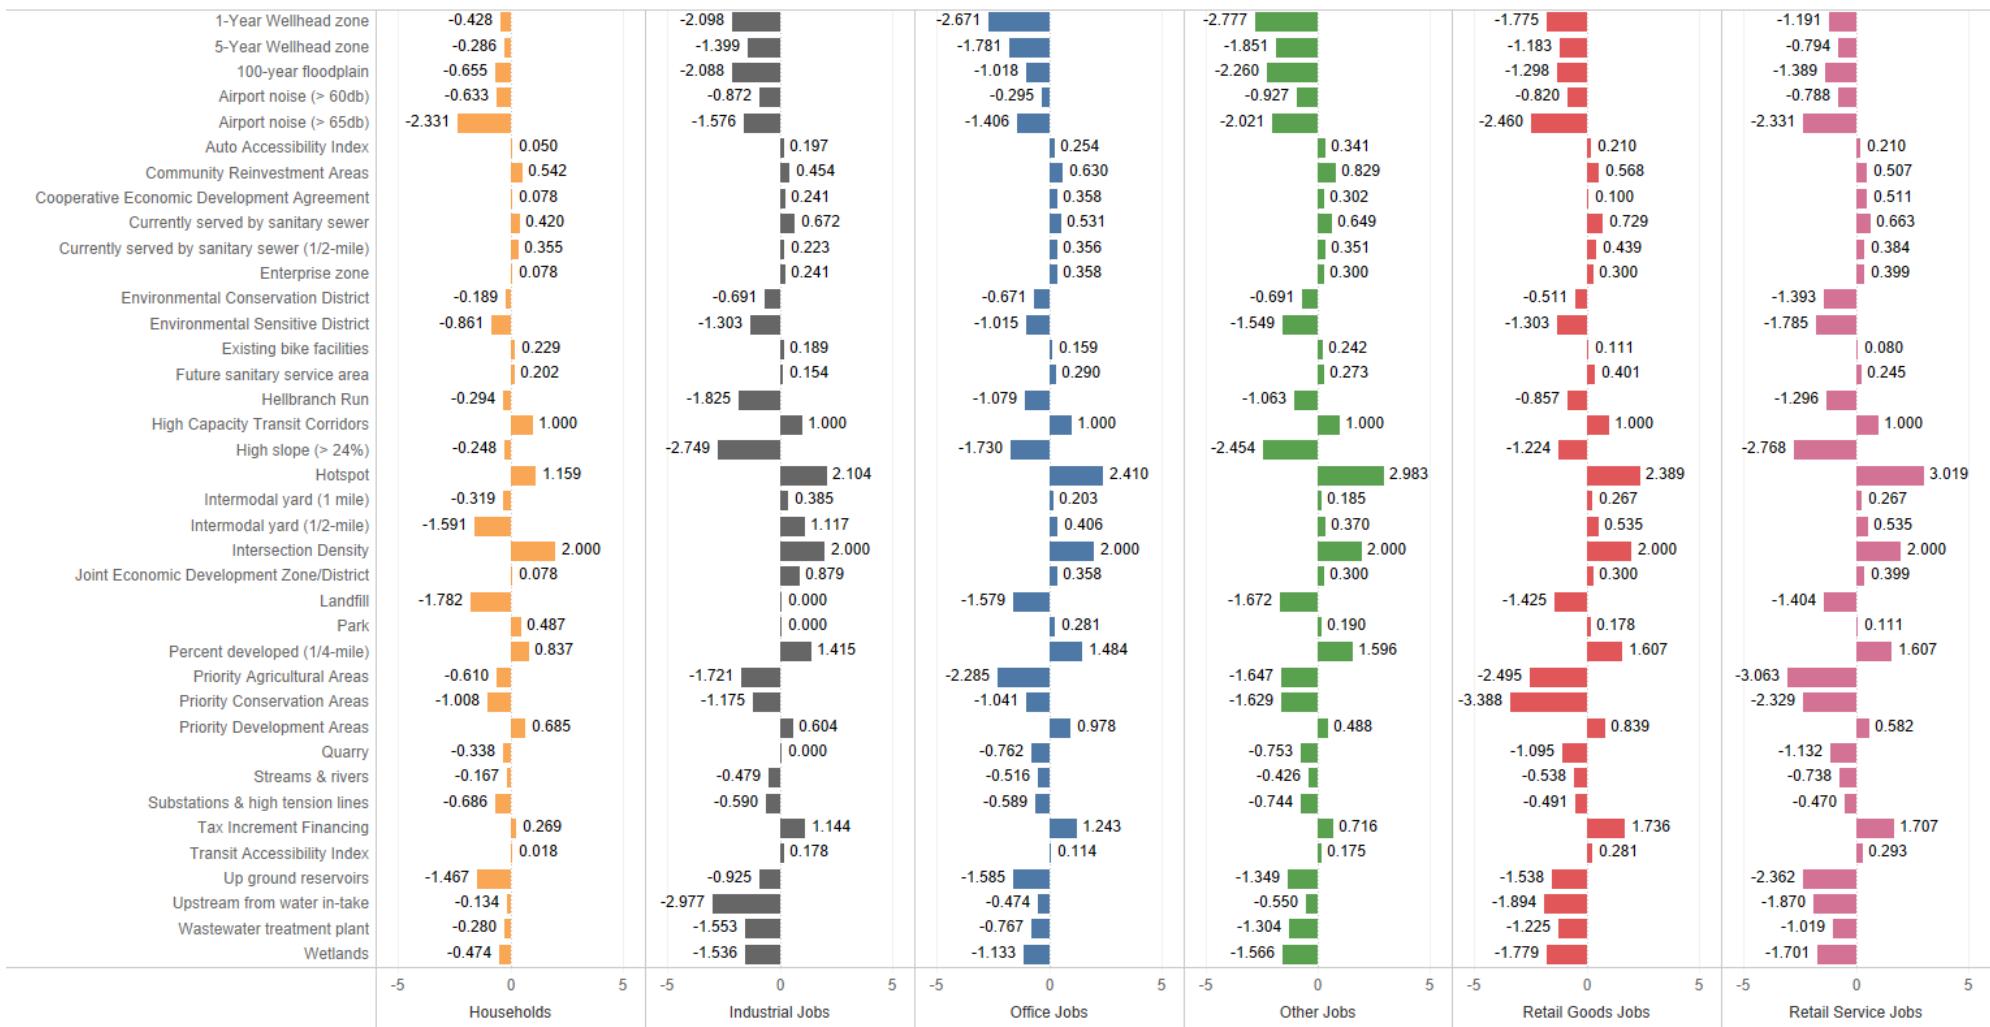

Figure 13. Land Use Allocation Criteria Values

Economic Development

Economic incentives include those areas where communities are either actively trying to attract development through an incentive such as tax increment financing or community reinvestment area designation, or through cooperative agreement with another community by way of such tools as a Cooperative Economic Development Agreement or a Joint Economic Development District. **Figure 14** is a display of these incentive areas.

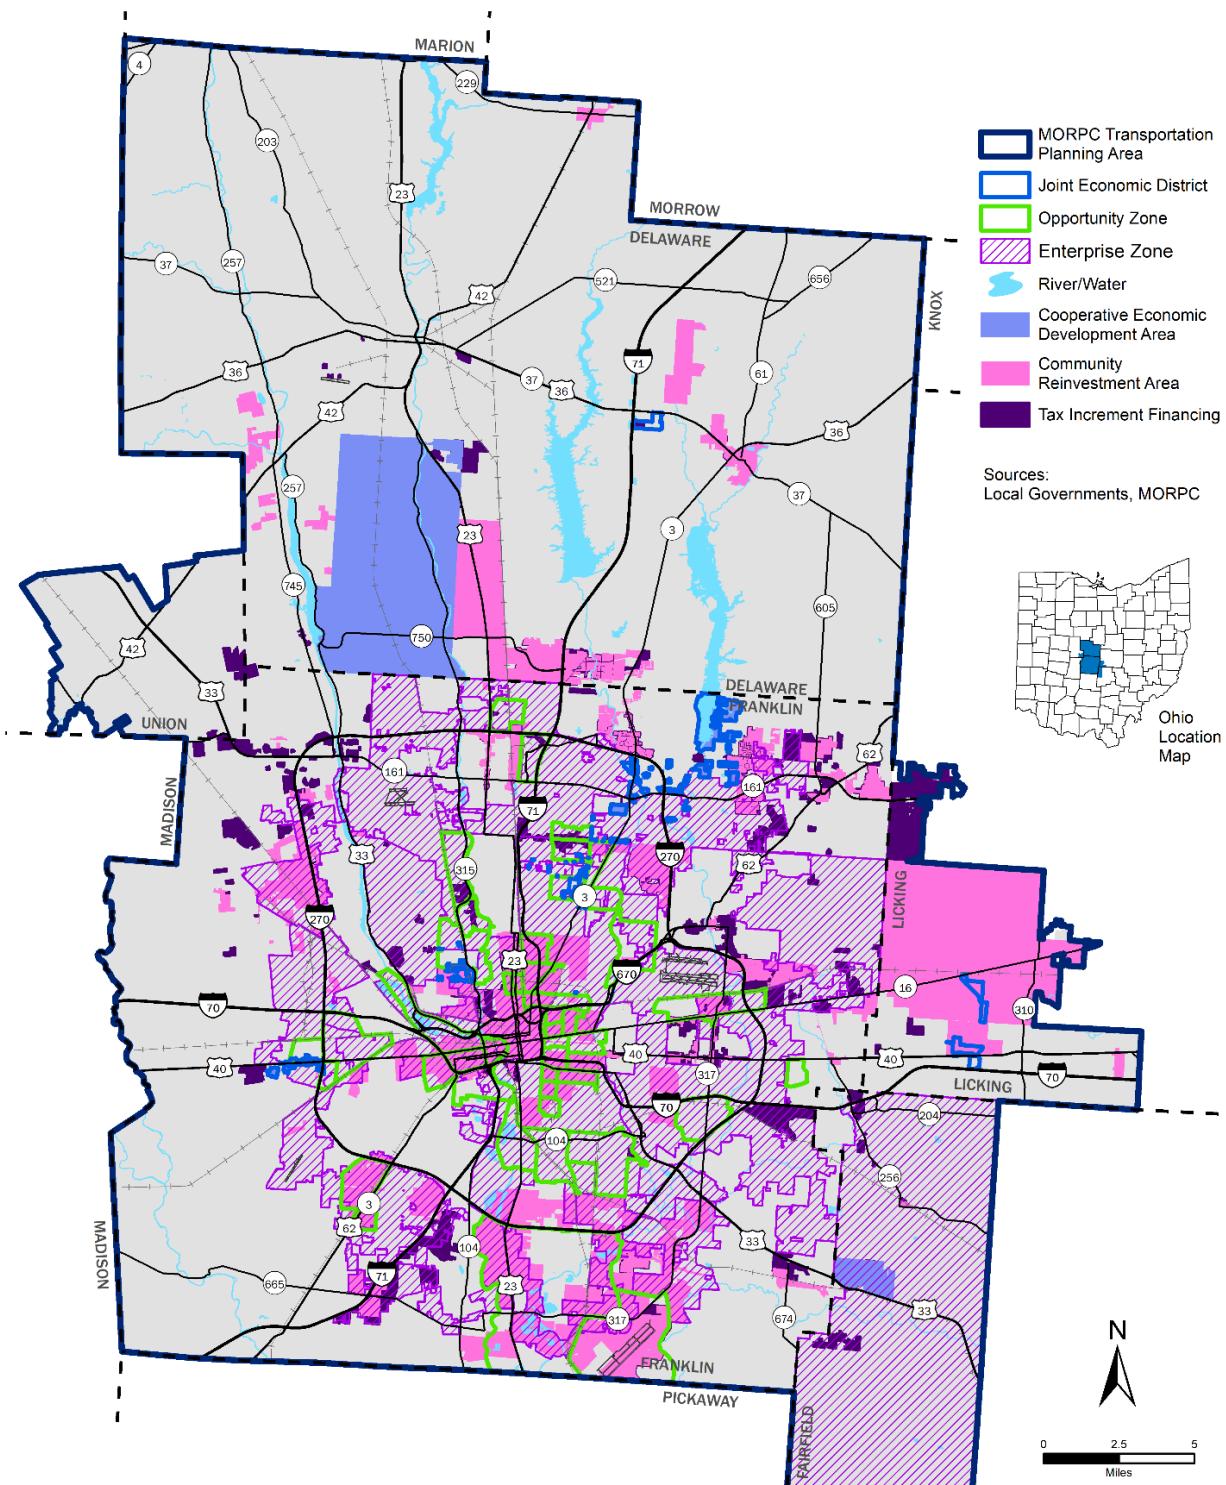

Figure 14. Economic Development Areas

Environmental Constraints

Keeping with preferred development policies outlined in documents including local land use plans, insight2050, and regional balanced growth plans, development was directed away from areas deemed to be environmentally sensitive. These include floodplains, wetlands, conserved lands, and agricultural lands. **Figure 15** shows environmentally sensitive areas.

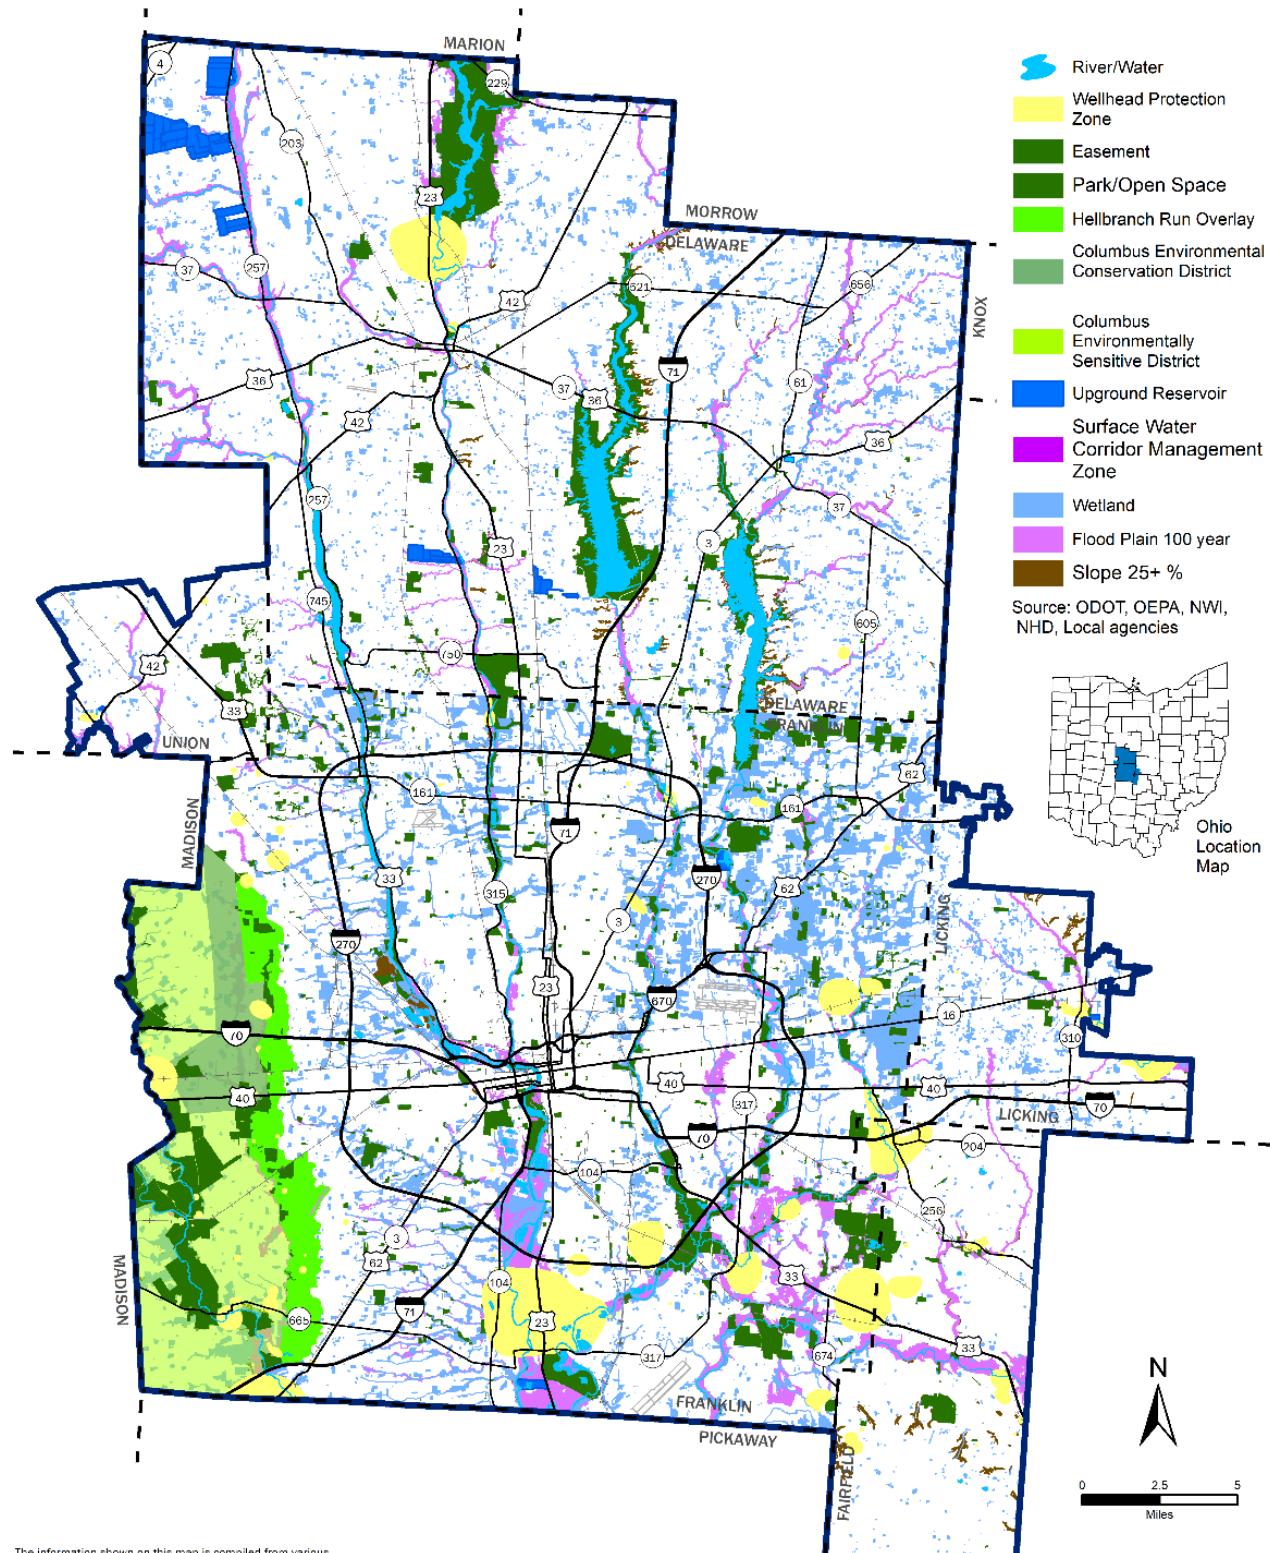

Figure 15. Environmental Constraints

Access to Infrastructure

Infrastructure includes transportation by auto, transit, bikeways and sidewalks. An accessibility measure was calculated based on opportunity for people to use automobiles to access the roadway system by using proximity to retail jobs as a surrogate for general travel needs. A similar analysis was conducted using the availability of the transit system and existing bike facilities. **Figures 16 & 17** show the transportation infrastructure used in these analyses.

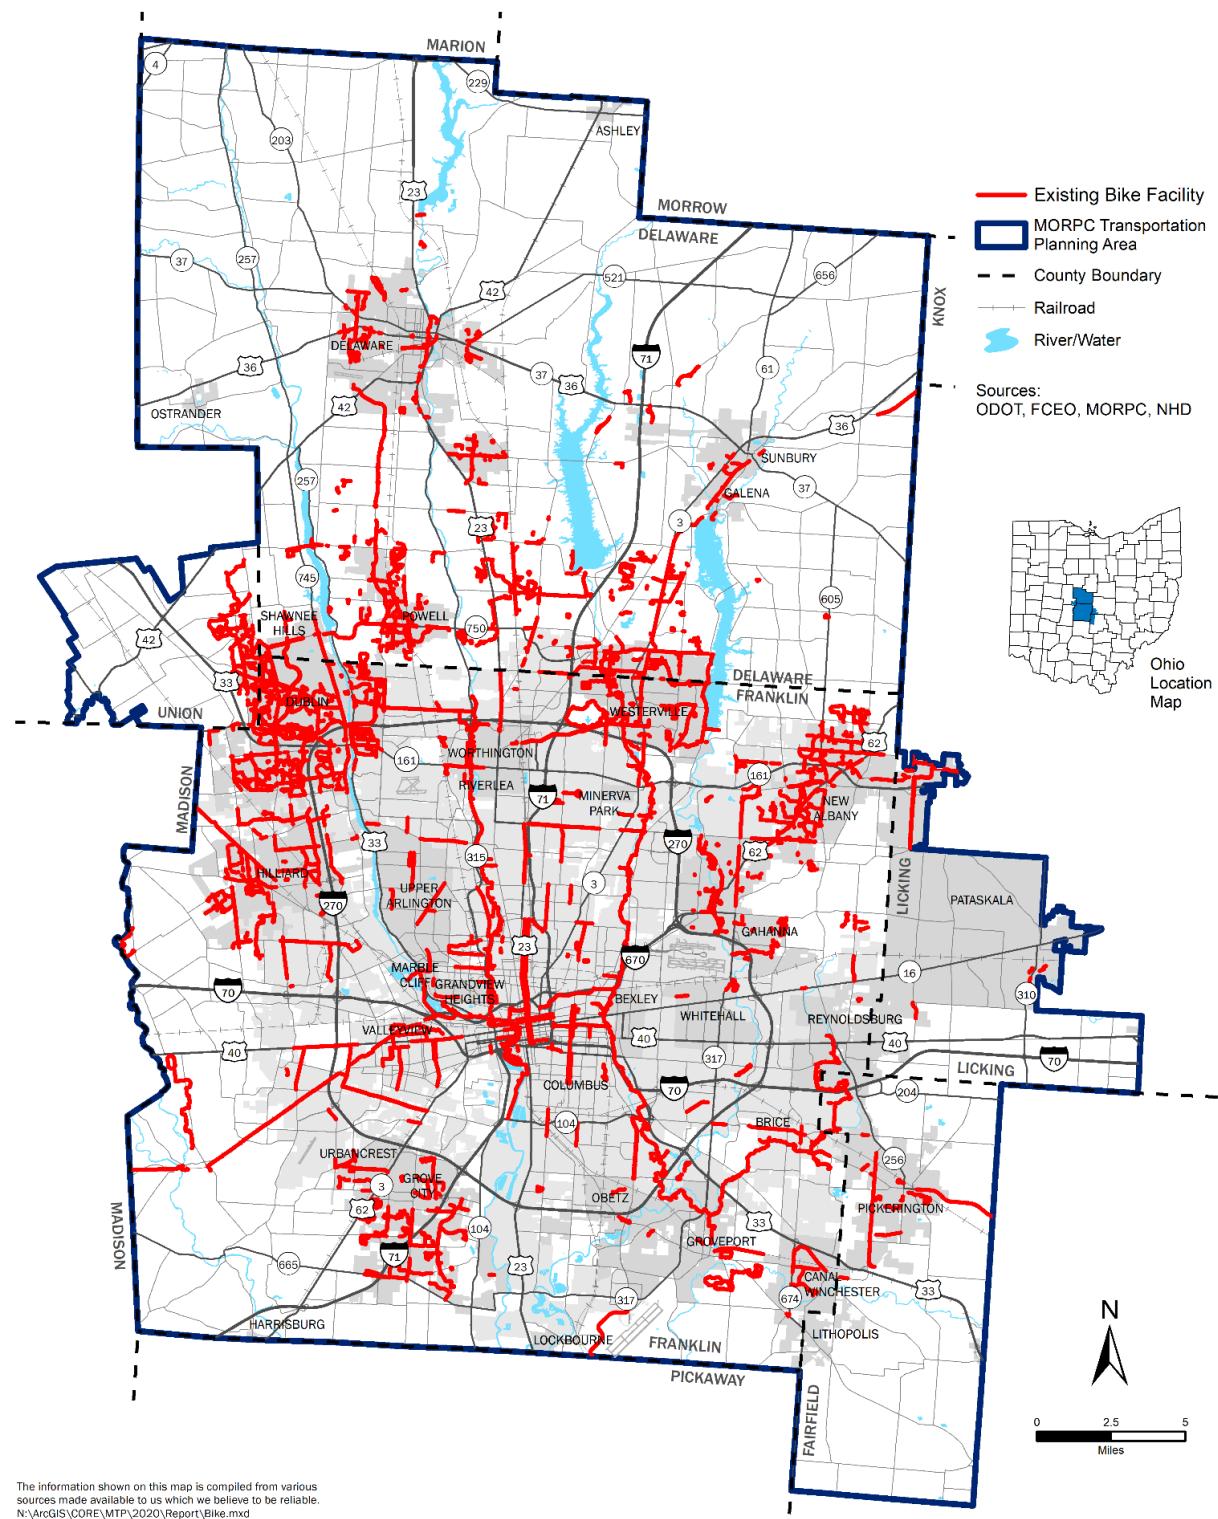

Figure 16. Bike Facilities

In addition to the calculated measures of car and transit access in the region, current cross-jurisdictional efforts to promote focused growth along five corridors to support high capacity transit (Corridor Concepts) were considered an important future driver for growth. As a result, these corridors (see **Figure 17**) were included as a factor that would attract growth of both jobs and residences in the region.

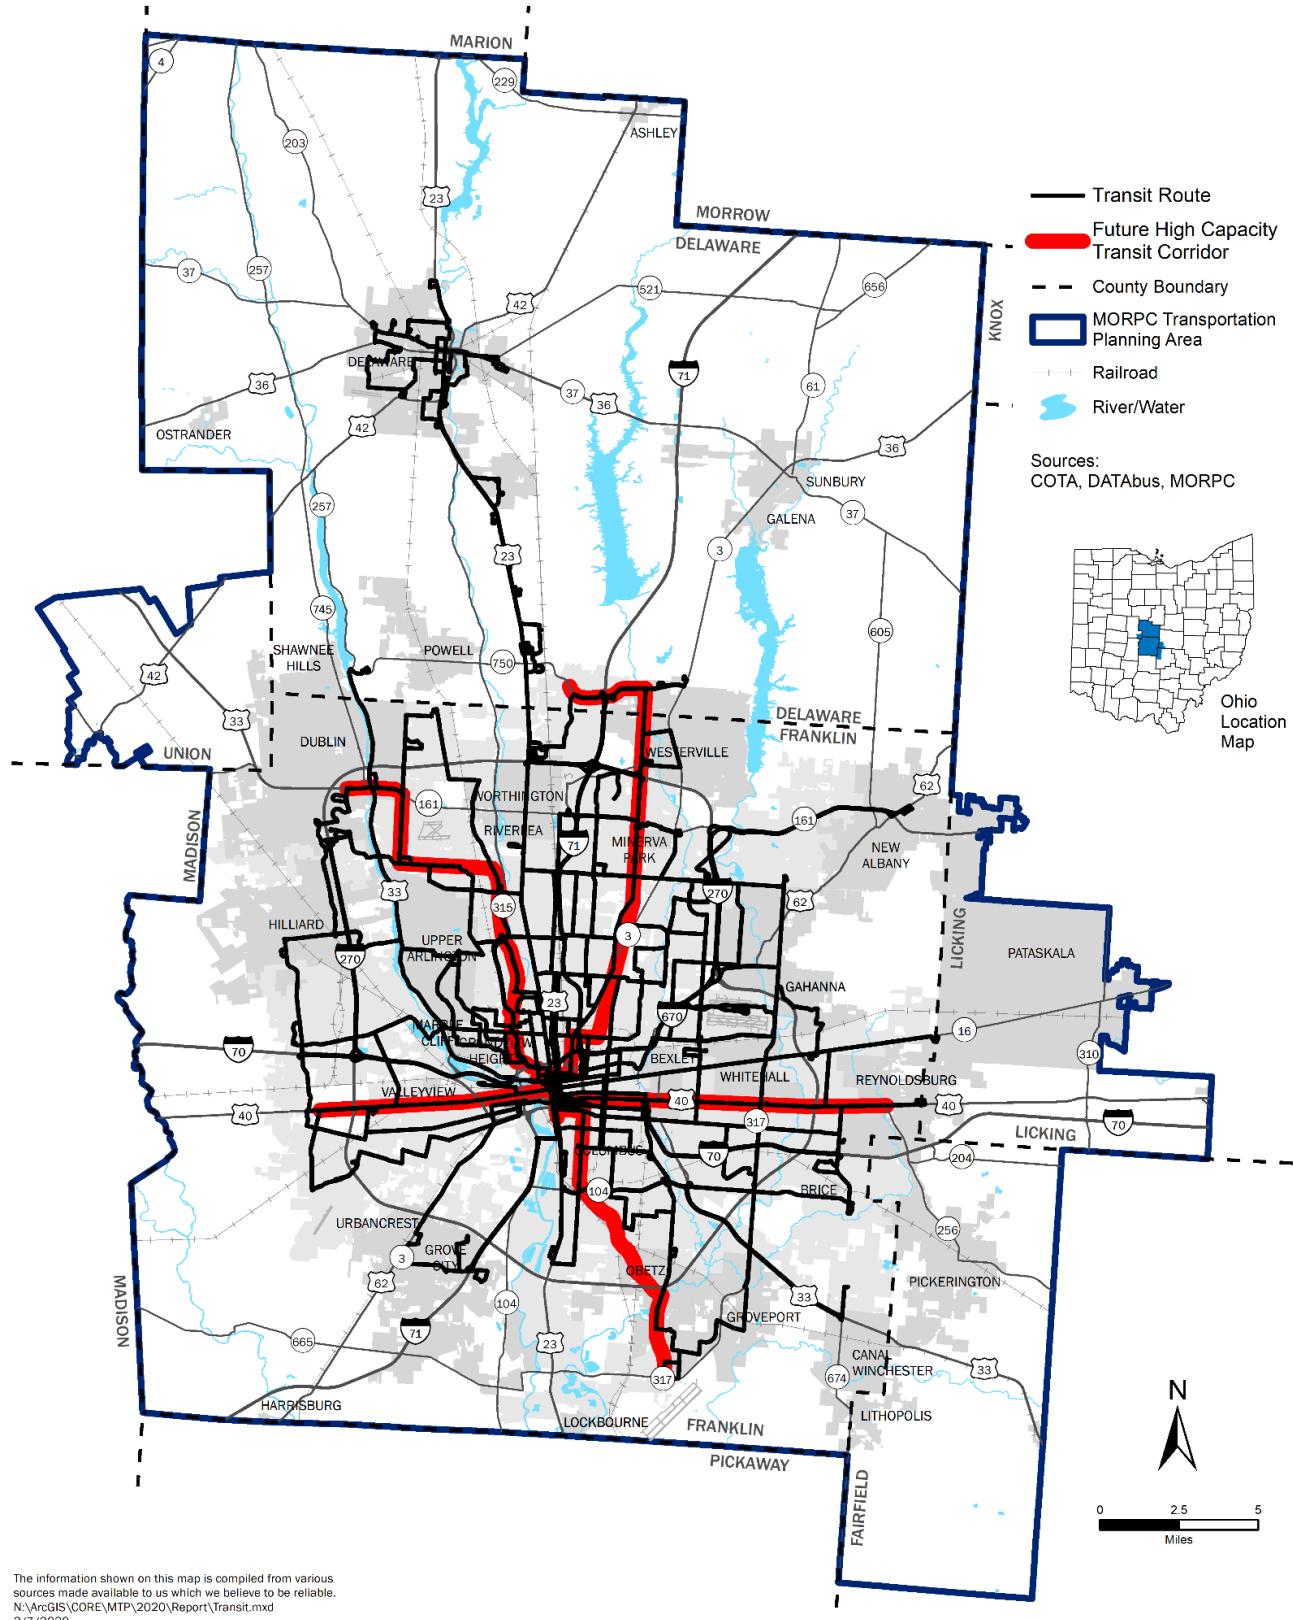

Figure 17. Existing Transit Routes & Future High Capacity Transit Routes

Another set of infrastructure includes public water and sanitary sewer systems (see **Figure 18**). MORPC collected existing and future sanitary sewer service areas from local providers. Sewer infrastructure data was used as a proxy for water service.

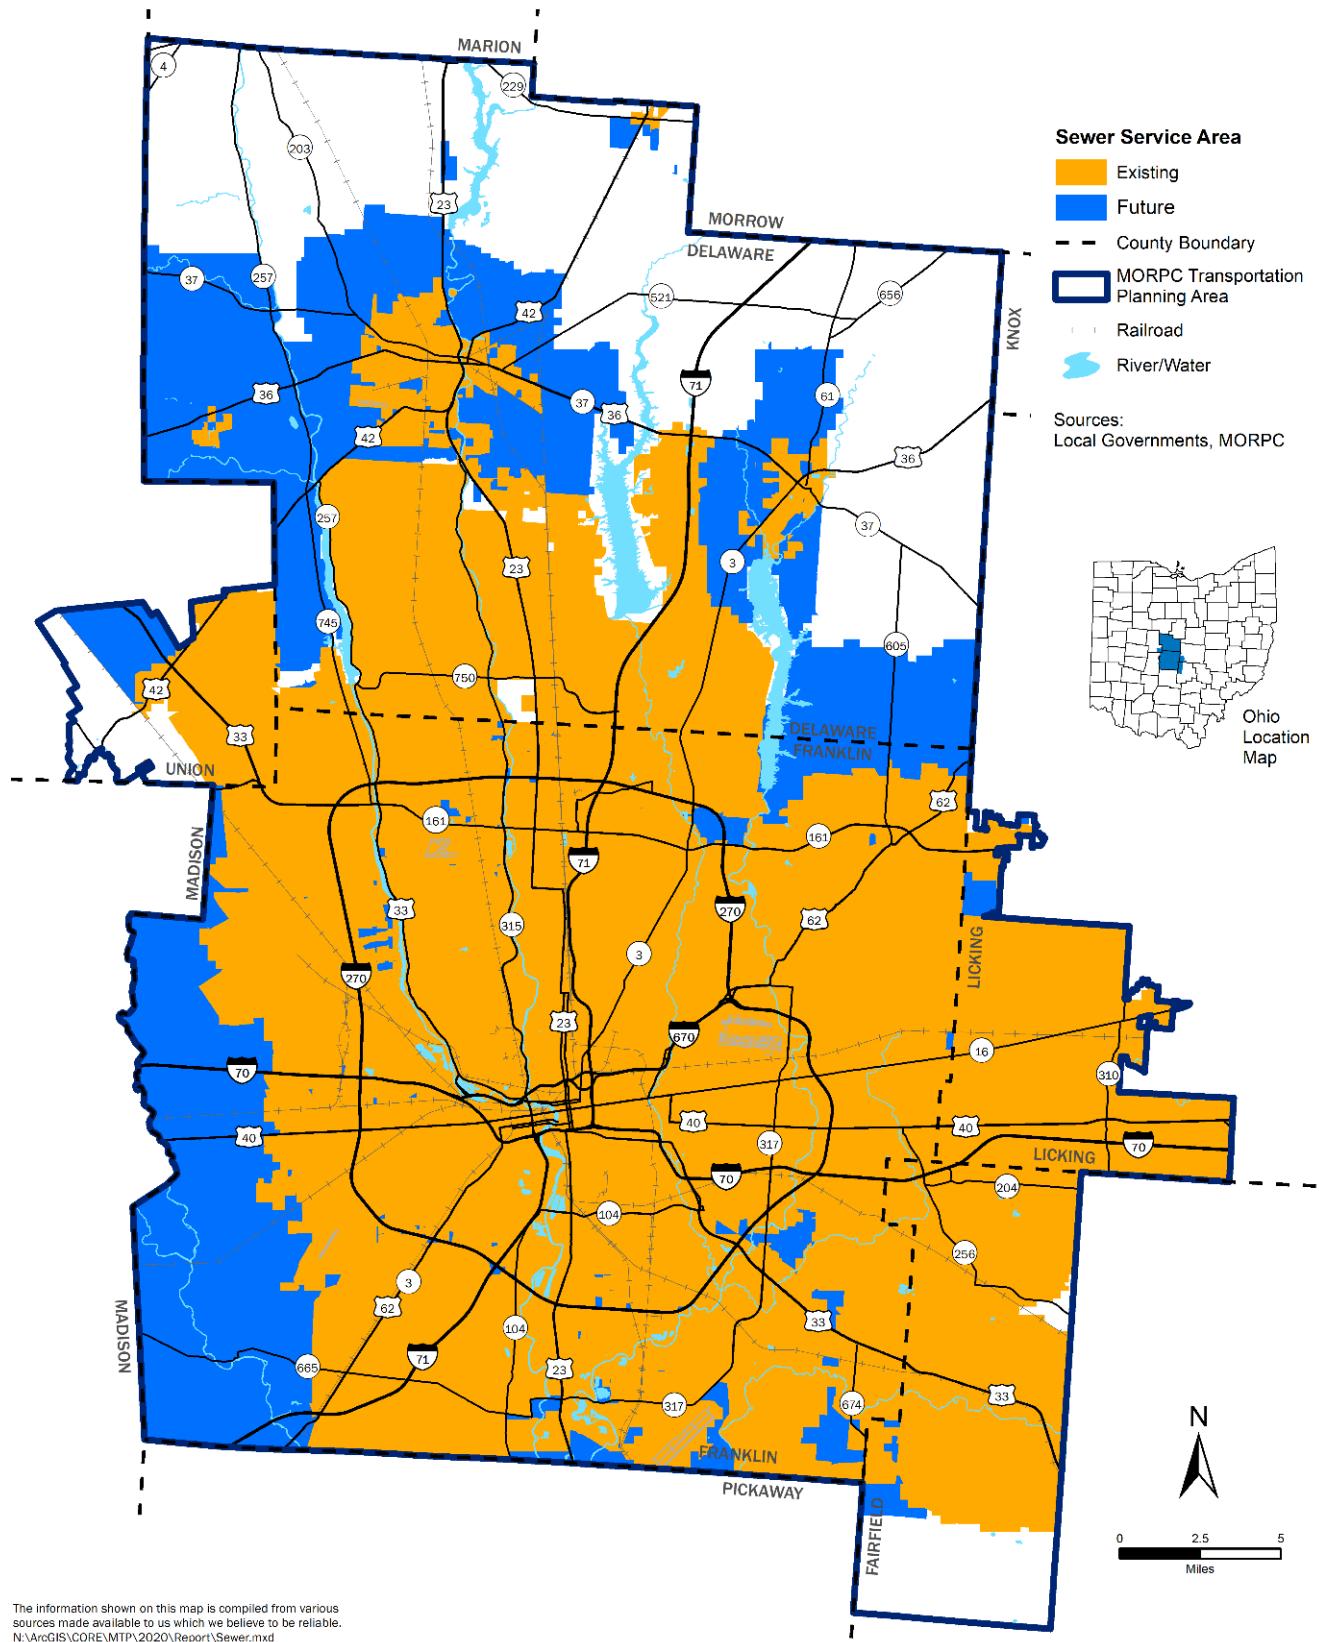

Figure 18. Existing and Proposed Sewer Service Areas

Areas adjacent to locations with development were defined and included as a criterion in order to model this relationship in forecasting future development. (see **Figure 19**)

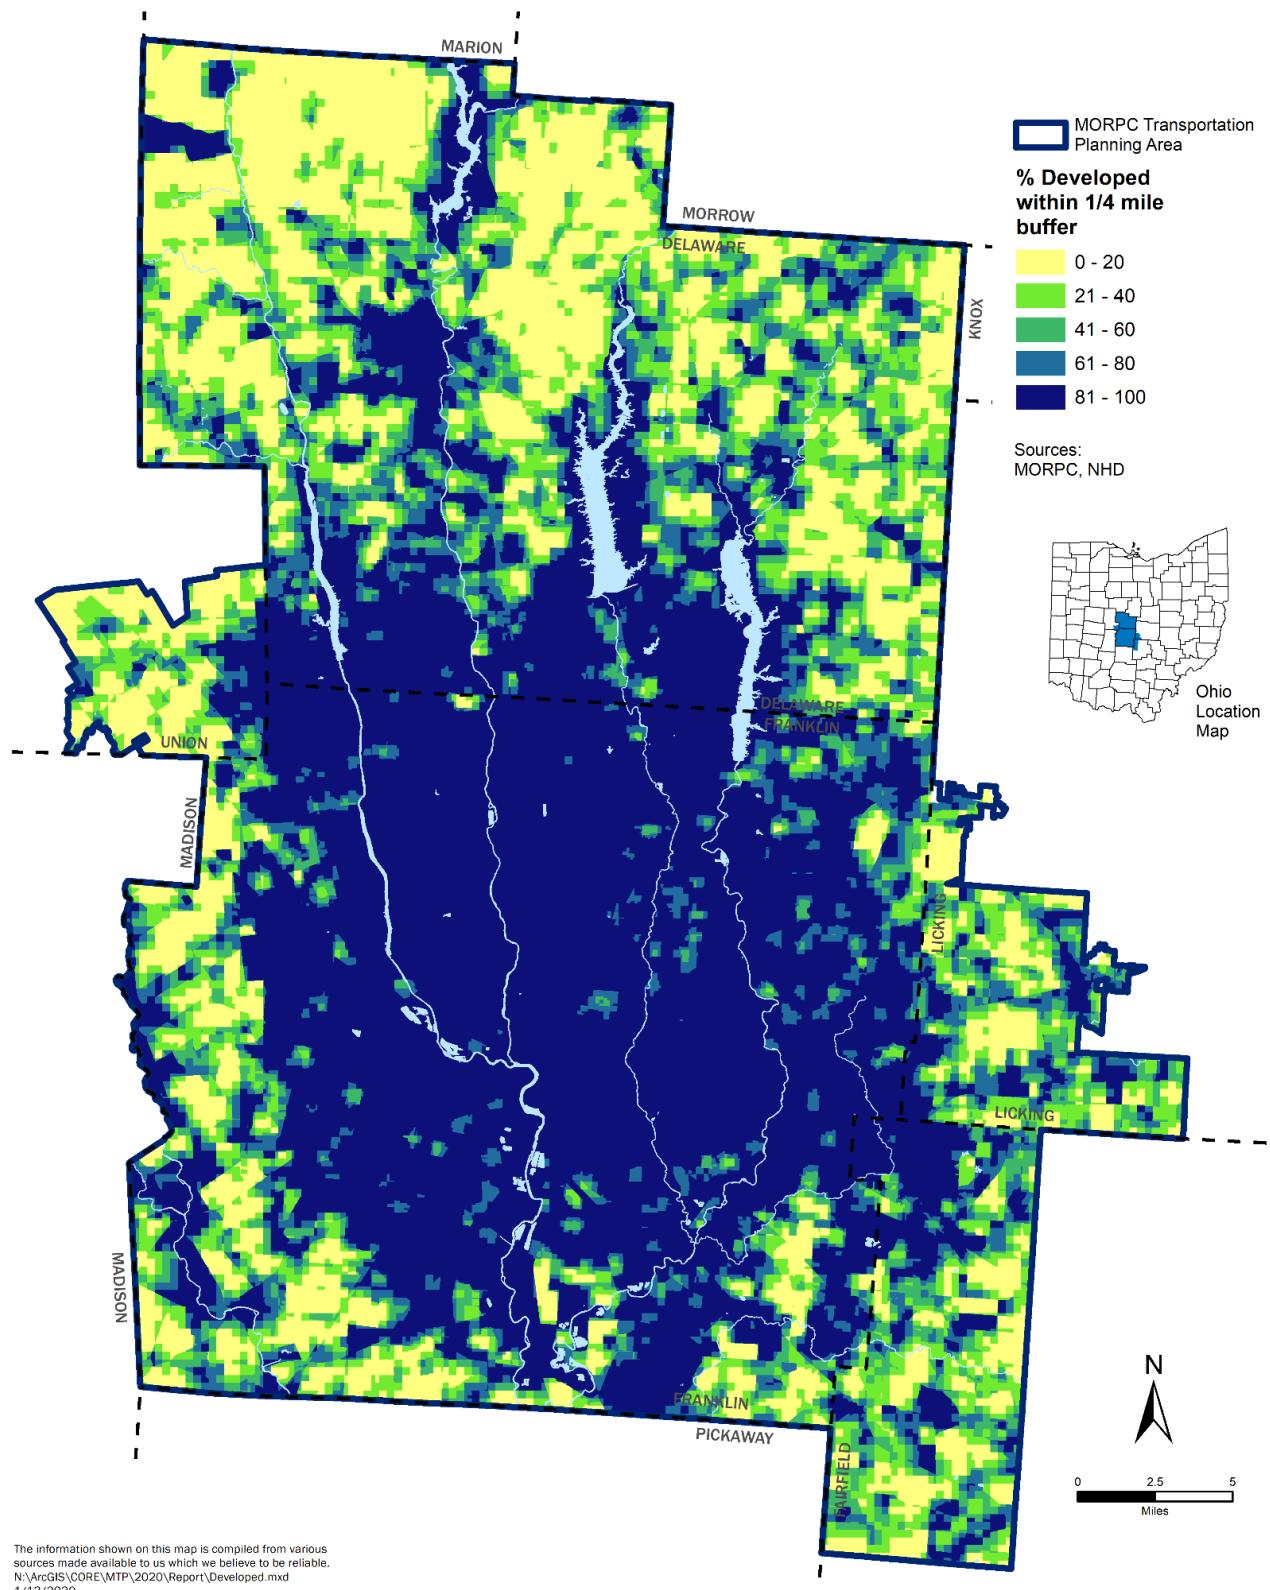

Figure 19. Developed Areas

Land Use Allocation Model

The *Land Use Allocation Model* produced forecasts that were developed using a *logit model*. This approach, which is new to MORPC for this MTP cycle, is designed to produce a range of outcomes, driven by the likelihood of possible outcomes--thereby accounting for the reality of uncertainty in development patterns.

The model evaluates each GridMAZ based on its *attractiveness* (see the [Criteria](#) section) using a utility function. This approach allows for many *simulations* of likely outcomes, using a method called *Monte Carlo Simulation*. This model ran 200 simulations and used the average of those as the final result. Using these two approaches--(1) data-driven calculation of criteria weights, and (2) producing many iterations of possible outcomes rather than a single ‘fixed’ outcome—the model is designed to mimic the likelihood that one area of land will be developed in favor of another.

The equation for calculating the likelihood that a given GridMAZ will attract a household or a job (in any one of the five MORPC job categories) based on the combined influence of all of the criteria characteristics in that GridMAZ is as follows:

$$Probability_{GridMAZ_i} = \frac{e^{Utility_{GridMAZ_i}}}{\sum_{j=1}^N e^{Utility_{GridMAZ_j}}}$$

$$Utility_{GridMAZ_i} = \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{3i} + \dots + \beta_n X_{ni}$$

Where:

$X_{1i,2i,\dots,ni}$ = Criteria for GridMAZ i

$\beta_{1,2,\dots,n}$ = Coefficients for criterion n

N = Total number of GridMAZ in the model area

The model also accounts for each GridMAZ growth capacity. A theoretical maximum number of jobs and households can be calculated based on the acres of land with a given land use type (in accordance with local land use plans—see [Future Land Use](#) section) and the density-based capacity for jobs or households associated with that land use (see [Capacities](#) section). The theoretical maximum minus any existing households or jobs in that location is the available capacity for either households or jobs (by MORPC job type).

In this process, the total number of households and jobs that could be allocated to all of the GridMAZ, was *controlled* to the projected growth in each county in the 7-county region (see the [County Growth Control Totals](#) section). While it is impossible to eliminate all uncertainty when projecting or forecasting growth, uncertainty can be mitigated by starting with larger areas with higher populations.

The control totals at the county level allow predictions for future growth to be modeled based on the demographic, and economic trends and forces that are likely to influence overall growth. This allows for a separate set of more detailed assumptions (around land use and development attractiveness) to be used to model a likely distribution of growth—precluding the need to incorporate broader demographic or economic assumptions at such a high level of geographic detail.

Projected growth in counties is not a ‘straight line’—both the demographic and economic trends that drive population growth are more likely to be cyclical than linear. As a result, the *Land Use Allocation Model* was run for 5-year increments from years 2020 – 2050. Each 5-year forecast accounts for the growth expected in a given county for that 5-year period only. Subsequent year forecasts then model the growth in the next 5-year period, accounting for the change in available capacity caused by the allocation of new jobs or households in the previous forecast year.

Example

As a practical example of the *Land Use Allocation Model* process described above, consider projected growth in Delaware County from 2025 to 2030. Based on the county growth projection methods, Delaware County is expected to add around 5,400 households and 4,000 jobs from 2025 to 2030.

For every single GridMAZ in Delaware County, there is an *available capacity* based on future land use types, land use capacities, and the number of existing jobs and housing units that are already occupying that total capacity. **Figure 20** is an example of that process using “*GridMAZ i*” to represent an hypothetical GridMAZ in Delaware County.

GridMAZ i has a maximum possible capacity of 555 jobs and 17 housing units based on its future land use types and their capacities. But suppose that there were already 200 jobs in *GridMAZ i* in 2018 (model base year), and that the forecast for 2025 allocated another 150 jobs to that location. That would mean that for the 2030 forecast year, *GridMAZ i* could receive up to 17 housing units and 155 jobs.

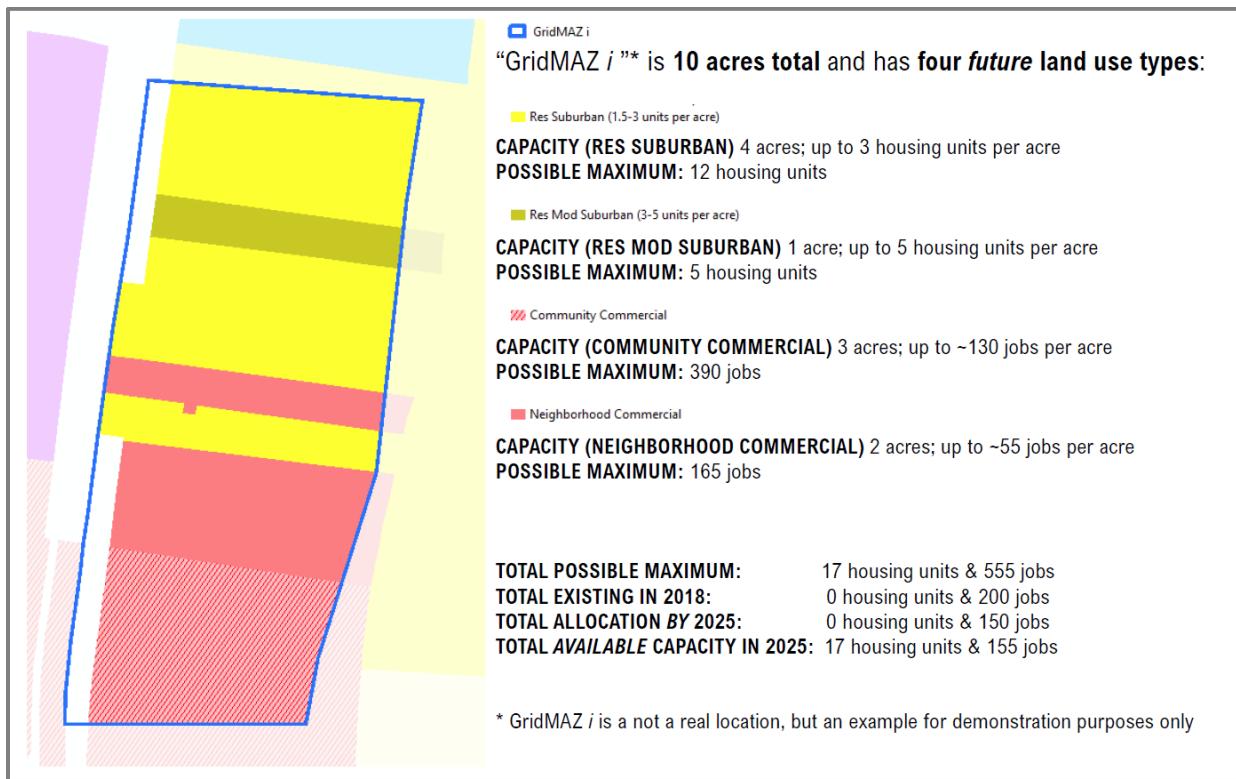

Figure 20. Example of Land Use Allocation Model Process

GridMAZ i, however, is one of many GridMAZ in the county, and only some of them will be developed with the 5,400 households and 4,000 jobs that are expected to be added in Delaware County during the 2025-2030 period. Assume that *GridMAZ i*, has criteria that make it a strong attractor of retail jobs. The *utility function* accounts for those strong criteria when allocating the limited number jobs and households possible in that county and period of time. As a result, in all 200 simulations of how the expected growth during this time period could be distributed, this GridMAZ is assigned some jobs. When the average of those 200 simulations is calculated, *GridMAZ i* is forecast to add another 100 jobs by 2030.

This example demonstrates what happens to a given GridMAZ in the *Land Use Allocation Model*. In the actual model, all of the GridMAZ are ‘allocated’ simultaneously in each model simulation.

Non-Land Use Variables

The land use allocation model predicts the locations of jobs and households in the future; however, the travel demand model requires additional variables to anticipate future travel patterns in the region. These variables are first projected at the county level (see [County Growth Control Totals](#) section). The land use model outputs (future households and jobs), and existing and future residential land use types are the primary inputs for determining how these variables will be allocated to small areas in the future. Each of the variables are predicted using methods and data inputs specific to what is being forecast, as outlined in the following descriptions. The variables are (1) household population, (2) group quarters population, (3) population by age, (4) workers by place of residence, (5) school enrollment, (6) household income, and (7) wages by job location.

Household Population

The land use model produces forecasts of households by GridMAZ. To estimate the future population in households by GridMAZ, existing year (2018) data was used in combination with existing land use data to determine the average household size by county and residential land use type (**Table 11**).

The existing average household size numbers were then used as ‘parameters’ to estimate future household population as a function of future households, land use type, and county. These estimates were controlled to the county household population control totals.

Table 11. Average Household Size by Residential Land Use and County

	Delaware	Fairfield	Franklin	Licking	Madison	Pickaway	Union
Rural Estate (5-20 acre lots)	2.72	2.85	2.75	2.69	2.81	2.80	2.63

High Suburban (5-8 units per acre)	2.49	2.66	2.56	2.49	2.48	2.57	2.52
Low Urban (8-20 units per acre)	2.27	2.44	2.39	2.47	2.45	2.63	2.45
High Urban Zone 3 (20-40 units per acre)	2.13	2.37	2.17	2.19	2.35	2.62	2.36
High Urban Zone 2 (40-80 units per acre)				2.03			
High Urban Zone 1 (80+ units per acre)				1.64			

Group Quarters Population

The U.S. Census Bureau defines types of *group quarters*, or residences other than households. The main types are student housing (e.g. dormitories), correctional facilities, and nursing homes. There are six broad types that were forecast in the Central Ohio region. The travel demand model requires predicted future locations of group quarters facilities and their populations.

In order to forecast future group quarters population, each group quarters type was categorized based on a likely pattern of future growth to determine one of two forecasting approaches to apply:

1. ***Grow in place***: increase in population is assumed to be added to population in existing locations. Projected growth in these categories in each county is distributed proportionally to each Traffic Analysis Zones containing the group quarters type.
2. ***Grow in new locations***: increase in population will likely be added to new facilities in new locations, with a greater likelihood in places with commercial development. Traffic Analysis Zones in the 98th percentile for retail job growth in each forecast year are identified from the land use model forecasts as candidates for new group quarters locations. Projected growth in these categories in each county is allocated (approximately 100 residents at a time) to the top-ranking candidate Traffic Analysis Zones.

Table 12. Group Quarters Population Growth by Type

Group Quarters Population Type	Forecast Approach	2018 – 2050 Growth
Correctional Facilities	Grow in place	3,690
Juvenile Facilities	Grow in place	140
Nursing Homes	Grow in new locations	3,300
Institutionalized – Other	Grow in place	90
College/University Student Housing	Grow in place	5,960
Non-Institutionalized – Other	Grow in new locations	1,360

Population by Age

The Travel Demand Model uses population in residences under 18 years old to model traffic flows between households and school locations. To estimate the future population under 18 in households by GridMAZ, existing year (2018) data was used in combination with existing parcel land use data, and American Community Survey estimates of population by age in block groups to determine, on average, the number of (1) people under 18, (2) people 18 – 64, and (3) people 65 and older by county and residential land use type (**Table 13**). All three age categories were estimated to ensure that estimates by age add up to total household population in each GridMAZ.

The existing average people in each age category per household numbers were then used as ‘parameters’ to estimate future population by age as a function of future household population, land use type, and county. These estimates were controlled to the county population by age control totals.

Table 13. Average Children Under 18 per Household by Residential Land Use Type and County

	Delaware	Fairfield	Franklin	Licking	Madison	Pickaway	Union
Rural Estate (5-20 acre lots)	0.66	0.71	0.70	0.63	0.68	0.69	0.64
Rural (2-5 acre lots)	0.68	0.69	0.66	0.62	0.66	0.69	0.62
Low Suburban (0.5 - 1.5 units per acre)	0.71	0.69	0.66	0.60	0.64	0.65	0.60
Suburban (1.5-3 units per acre)	0.77	0.65	0.67	0.55	0.59	0.68	0.65
Moderate Suburban (3-5 units per acre)	0.76	0.76	0.66	0.61	0.62	0.65	0.70
High Suburban (5-8 units per acre)	0.65	0.72	0.66	0.61	0.57	0.60	0.61
Low Urban (8-20 units per acre)	0.54	0.56	0.56	0.65	0.58	0.64	0.60
High Urban Zone 3 (20-40 units per acre)	0.47	0.59	0.36	0.43	0.60	0.63	0.51
High Urban Zone 2 (40-80 units per acre)				0.28			
High Urban Zone 1 (80+ units per acre)				0.06			

Workers by Place of Residence

The Travel Demand Model uses the population of employed workers in residences to model traffic flows between households and work locations. To estimate the future population of workers in residences by GridMAZ, existing year (2018) data was used in combination with existing parcel land use data, and American Community Survey estimates of employed workers in block groups to determine, on average, the average number of workers per household by county and residential land use type (**Table 14**).

The existing average workers per household numbers were then used as parameters to estimate future worker population as a function of future household population, land use type, and county. These estimates were controlled to the county worker population control totals.

Table 14. Average Workers per Household by Residential Land Use Type and County

	Delaware	Fairfield	Franklin	Licking	Madison	Pickaway	Union
Rural Estate (5-20 acre lots)	1.43	1.35	1.45	1.40	1.36	1.43	1.34
Rural (2-5 acre lots)	1.41	1.33	1.42	1.40	1.35	1.40	1.35
Low Suburban (0.5 - 1.5 units per acre)	1.39	1.35	1.35	1.39	1.33	1.38	1.34
Suburban (1.5-3 units per acre)	1.40	1.37	1.33	1.30	1.32	1.37	1.33
Moderate Suburban (3-5 units per acre)	1.38	1.40	1.31	1.27	1.24	1.35	1.35

Low Urban (8-20 units per acre)	1.19	1.16	1.23	1.11	1.20	1.31	1.26
High Urban Zone 3 (20-40 units per acre)	1.18	1.19	1.25	1.04	1.13	1.47	1.35
High Urban Zone 2 (40-80 units per acre)			1.23				
High Urban Zone 1 (80+ units per acre)			1.10				

School Enrollment

The Travel Demand Model uses school enrollment to model traffic flows between households and school locations. To estimate future school enrollment by MAZ, existing year (2018) public and private school enrollment data (for grades Kindergarten through 8, and 9 through 12) was used in combination with American Community Survey estimates of population that correspond with the modeled grade levels (ages 5 – 14 were used as a proxy for students enrolled in grades K – 8, and ages 15 – 17 were used as a proxy for students enrolled in grades 9 – 12) in block groups, and county level projections of those age groups to determine the relationship between residential school age population and enrollment by school district.

Enrollment in grades (K-8 and 9-12) was projected at the county level as a function of county level projections of the corresponding proxy age categories, assuming fixed rates of enrollment for those age categories in the future. Enrollment in public versus private schools was assumed to remain in proportion with the base year enrollment data. Projected county enrollment in each of these categories was then distributed to school districts based on district school age population growth.

Building-level public school enrollment data was used to calculate a typical enrollment ‘threshold’ in school buildings by district and grade level. In future years (modeled in 5-year increments to year 2050), predicted growth in district enrollment was allocated, either to existing public school buildings (allowing buildings to grow to up to 125% of the average building enrollment in the base year data), or to new buildings if all buildings within a given district are at or above their enrollment capacity.

When a new school building location was ‘triggered’ according to the condition described above, a new school building location was identified. In these instances, School Attendance Boundary data was used to determine which area within a district would have the greatest growth in school age population. Finally, a MAZ with the greatest non-industrial job growth was selected as the most-likely location for a new school. To model the likely reality that a new school would also be used to redistribute over-crowding in existing locations, enrollment was re-allocated across all buildings in the district, including the new location.

Growth in private enrollment was assigned to new locations in MAZ with the greatest non-industrial job growth.

Household Income

The Travel Demand Model assumes relationships between work and home locations by relating average household income (residences) to average wages (workplaces). Future average household income in Traffic Analysis Zones was conducted by forecasting growth in Census Tracts, then interpolating those forecast numbers to Traffic Analysis Zones.

Average household income by Census Tracts was inflation adjusted to 2010 dollars and assigned to standardized geographies (using the Longitudinal Tract Database) using 2000 decennial Census data, and 2013 – 2017 American Community Survey estimates.

The compound average growth rate (CAGR) was calculated for each Tract and was applied to 5-year incremental forecast years from 2020 – 2050. The predicted average household income in Tracts was then assigned to Traffic Analysis Zones using areal interpolation. All values were adjusted for inflation to 2010 dollars.

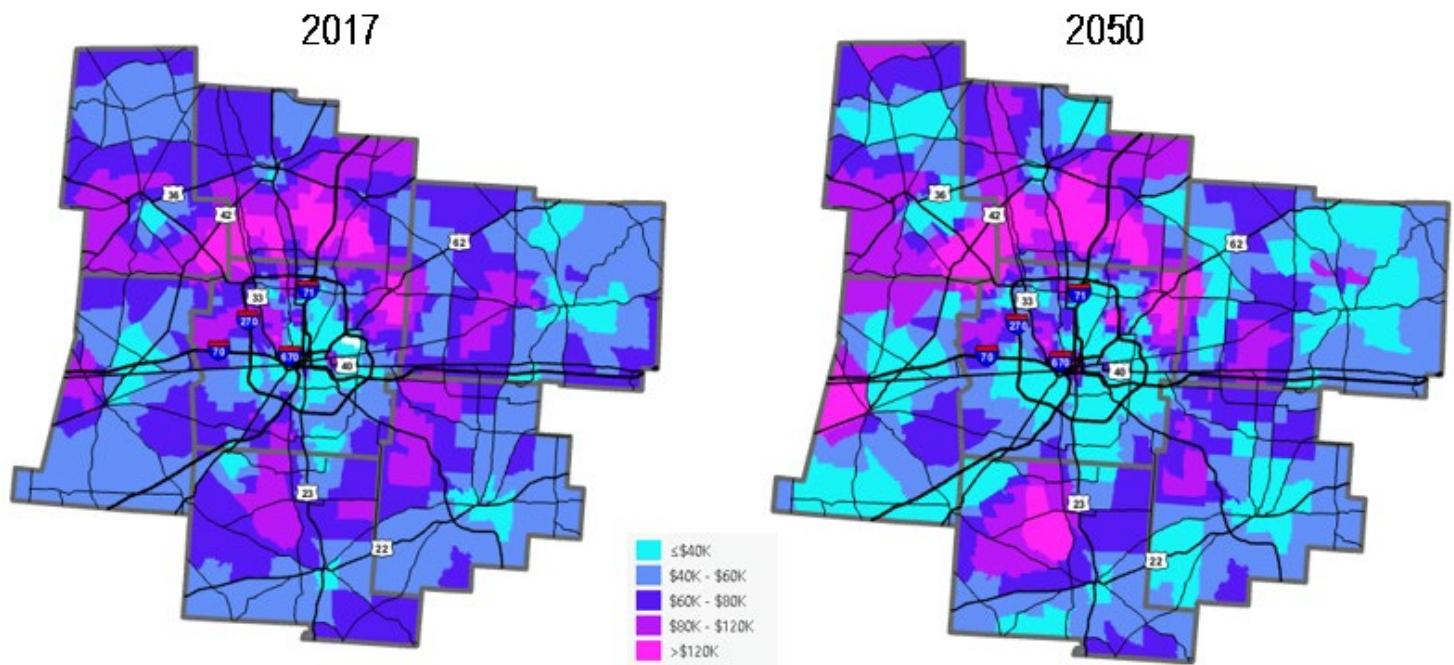

Figure 21. Change in Average Household Income

Wages by Job Location

The Travel Demand Model assumes relationships between work and home locations by relating average household income (residences) to average wages (workplaces). Future wages in job locations was forecasted by using average wages by industry sector and by county and applying those averages to forecasted employment growth.

Two sources were used to estimate average wages by industry sector (NAICS 2-digit classification) and by county (summarized in **Table 16**):

1. In most cases (n=157), 2018 Quarterly Census of Employment and Wages (QCEW) annual average worker wages were available by county and industry sector, as published by the Bureau of Labor Statistics.
2. In instances where the data were suppressed, U.S. Census Bureau 2016 County Business Pattern wage estimates by industry sector and county were used, if available (n=4).
3. Finally, in instances where data were suppressed in both datasets (n=14), the average wages in counties with known average wages were calculated for an industry sector and used as an estimate for the missing locations.

Table 16. Average Wages by County and Industry Sector

Note: Wages rounded to hundreds and adjusted for inflation to 2010 dollars

The average wage values were used as coefficients to apply to future jobs by Micro Analysis Zones (MAZ), using the following equation:

$$\text{Average Wage}_{MAZ_i} = \frac{\text{Total Wages}_{MAZ_i}}{\text{Total Employment}_{MAZ_i}}$$
$$\text{Total Wages}_{MAZ_i} = \beta_1 X_{1i} + \beta_2 X_{2i} + \beta_3 X_{3i} + \dots + \beta_n X_{ni}$$

Where:

$X_{1i,2i\dots ni}$ = Estimated jobs in MAZi for industry sector n

$\beta_{1,2\dots n}$ = Average wages for industry sector n

The land use model forecasts jobs by MORPC industry category, rather than by NAICS industry sector (this is described in more detail in the [Employment](#) section). A process called *Iterative Proportional Fitting* was used to convert the broad industry jobs forecasts into NAICS sectors using existing data, when available for a given MAZ (2018 Quarterly Census of Employment and Wages establishment-level data). In cases where the profile of jobs in a MAZ was very different in the future than the profile of jobs in the base year, a process was used to identify MAZ in the existing data with similar characteristics to then assign a mix of jobs by NAICS sector to that MAZ in the future.

Community Input

Local governments were invited, at various steps in the process to provide comments or edit suggestions on data inputs and model results. Web maps and GIS data layers were made available to key staff representing all communities in the 7-county region. This input was one element of a due diligence effort to ensure the most accurate and up-to-date data possible.

Model Results

Growth by TAZ from 2018 - 2050

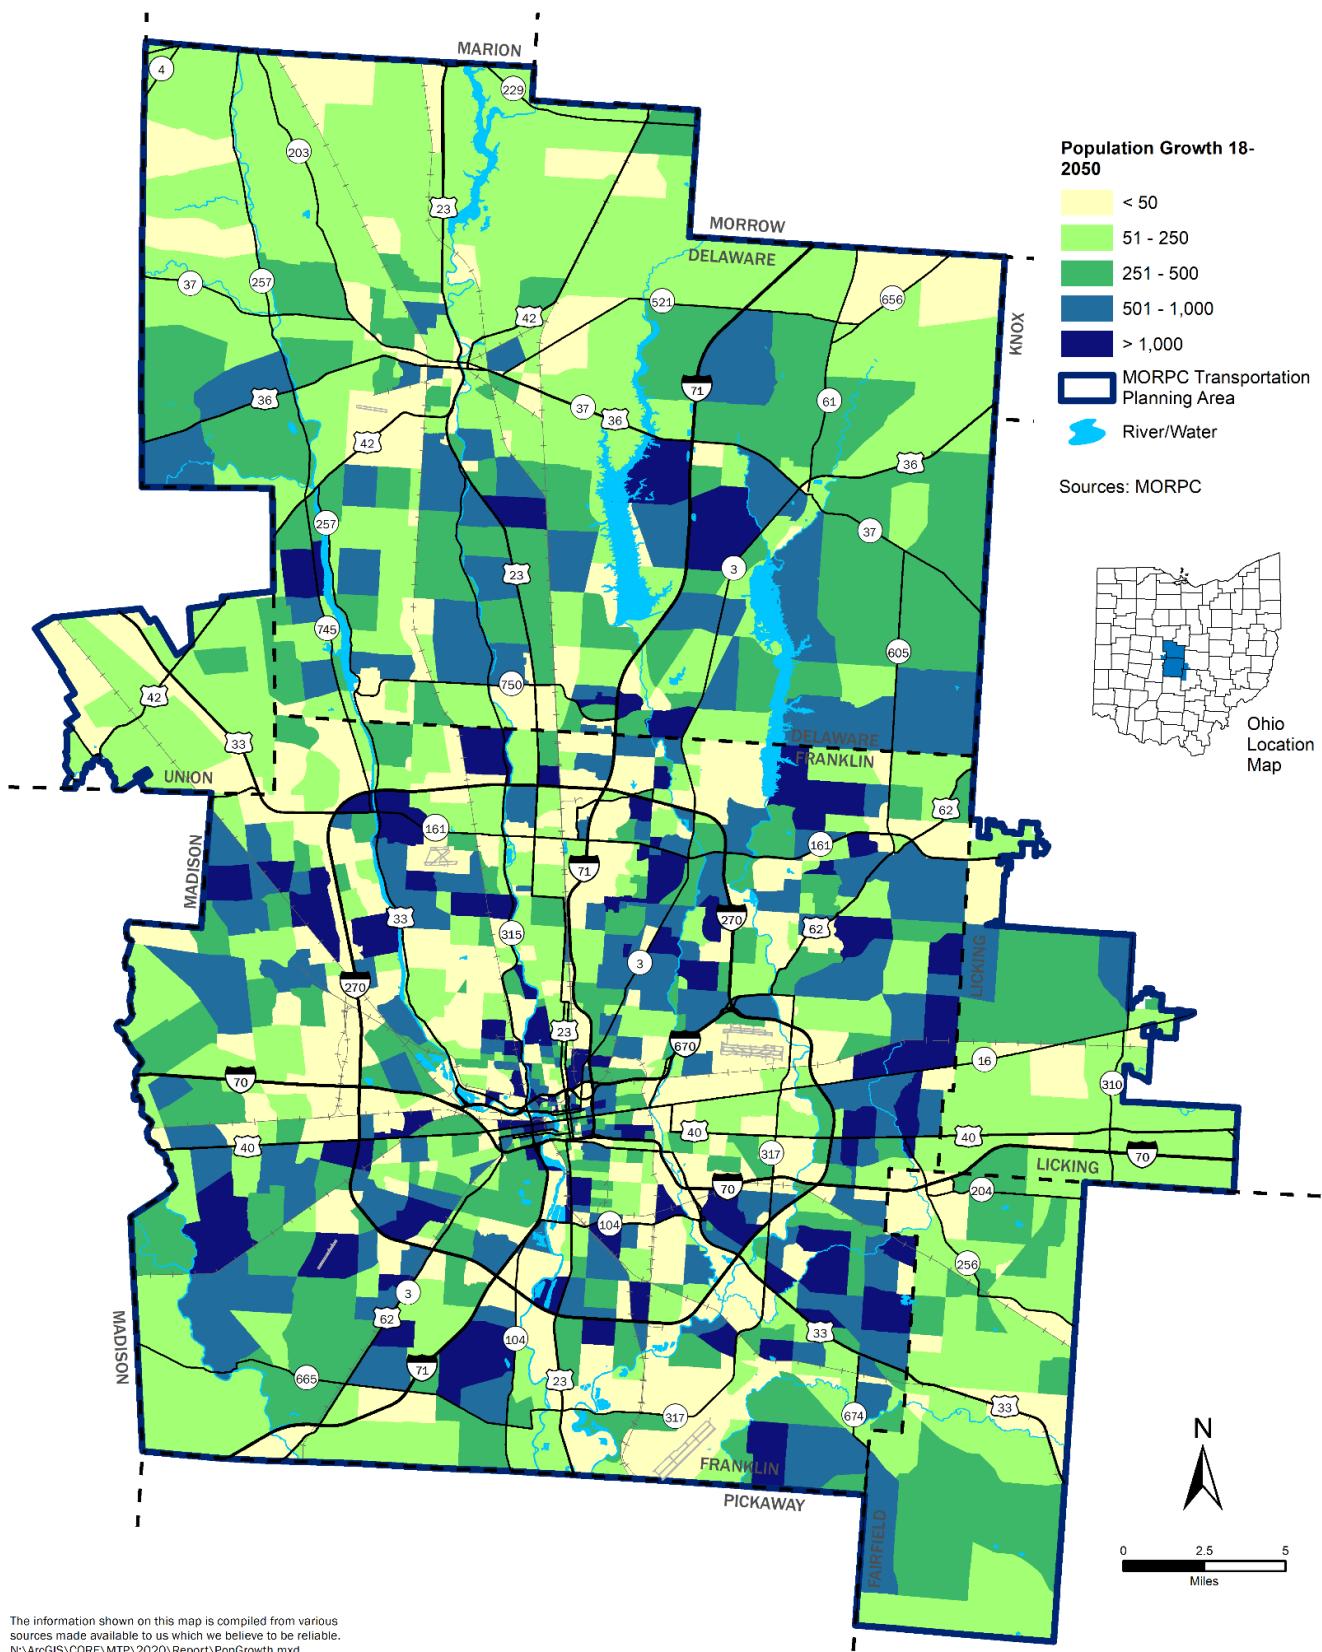

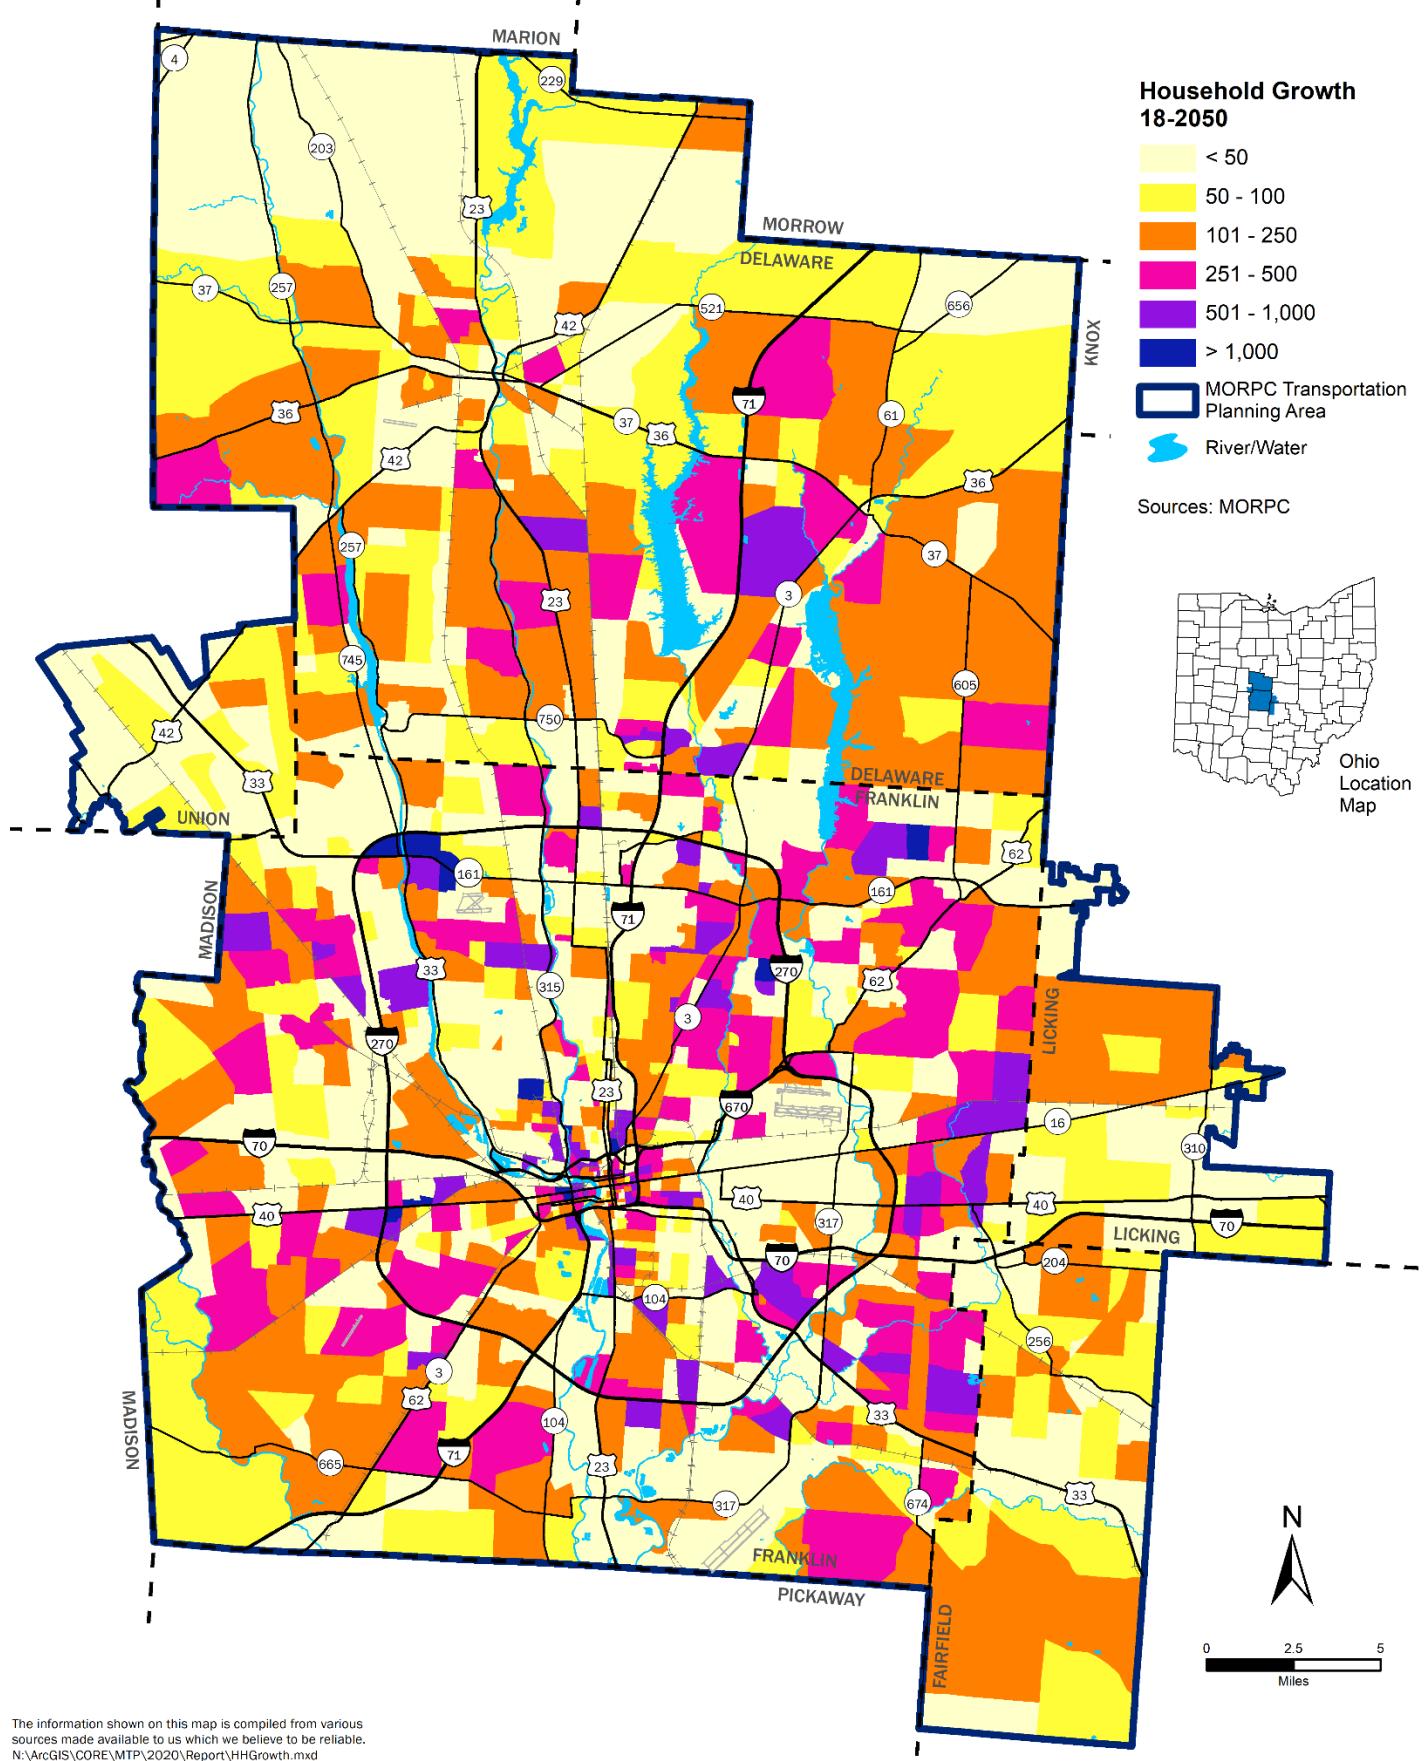

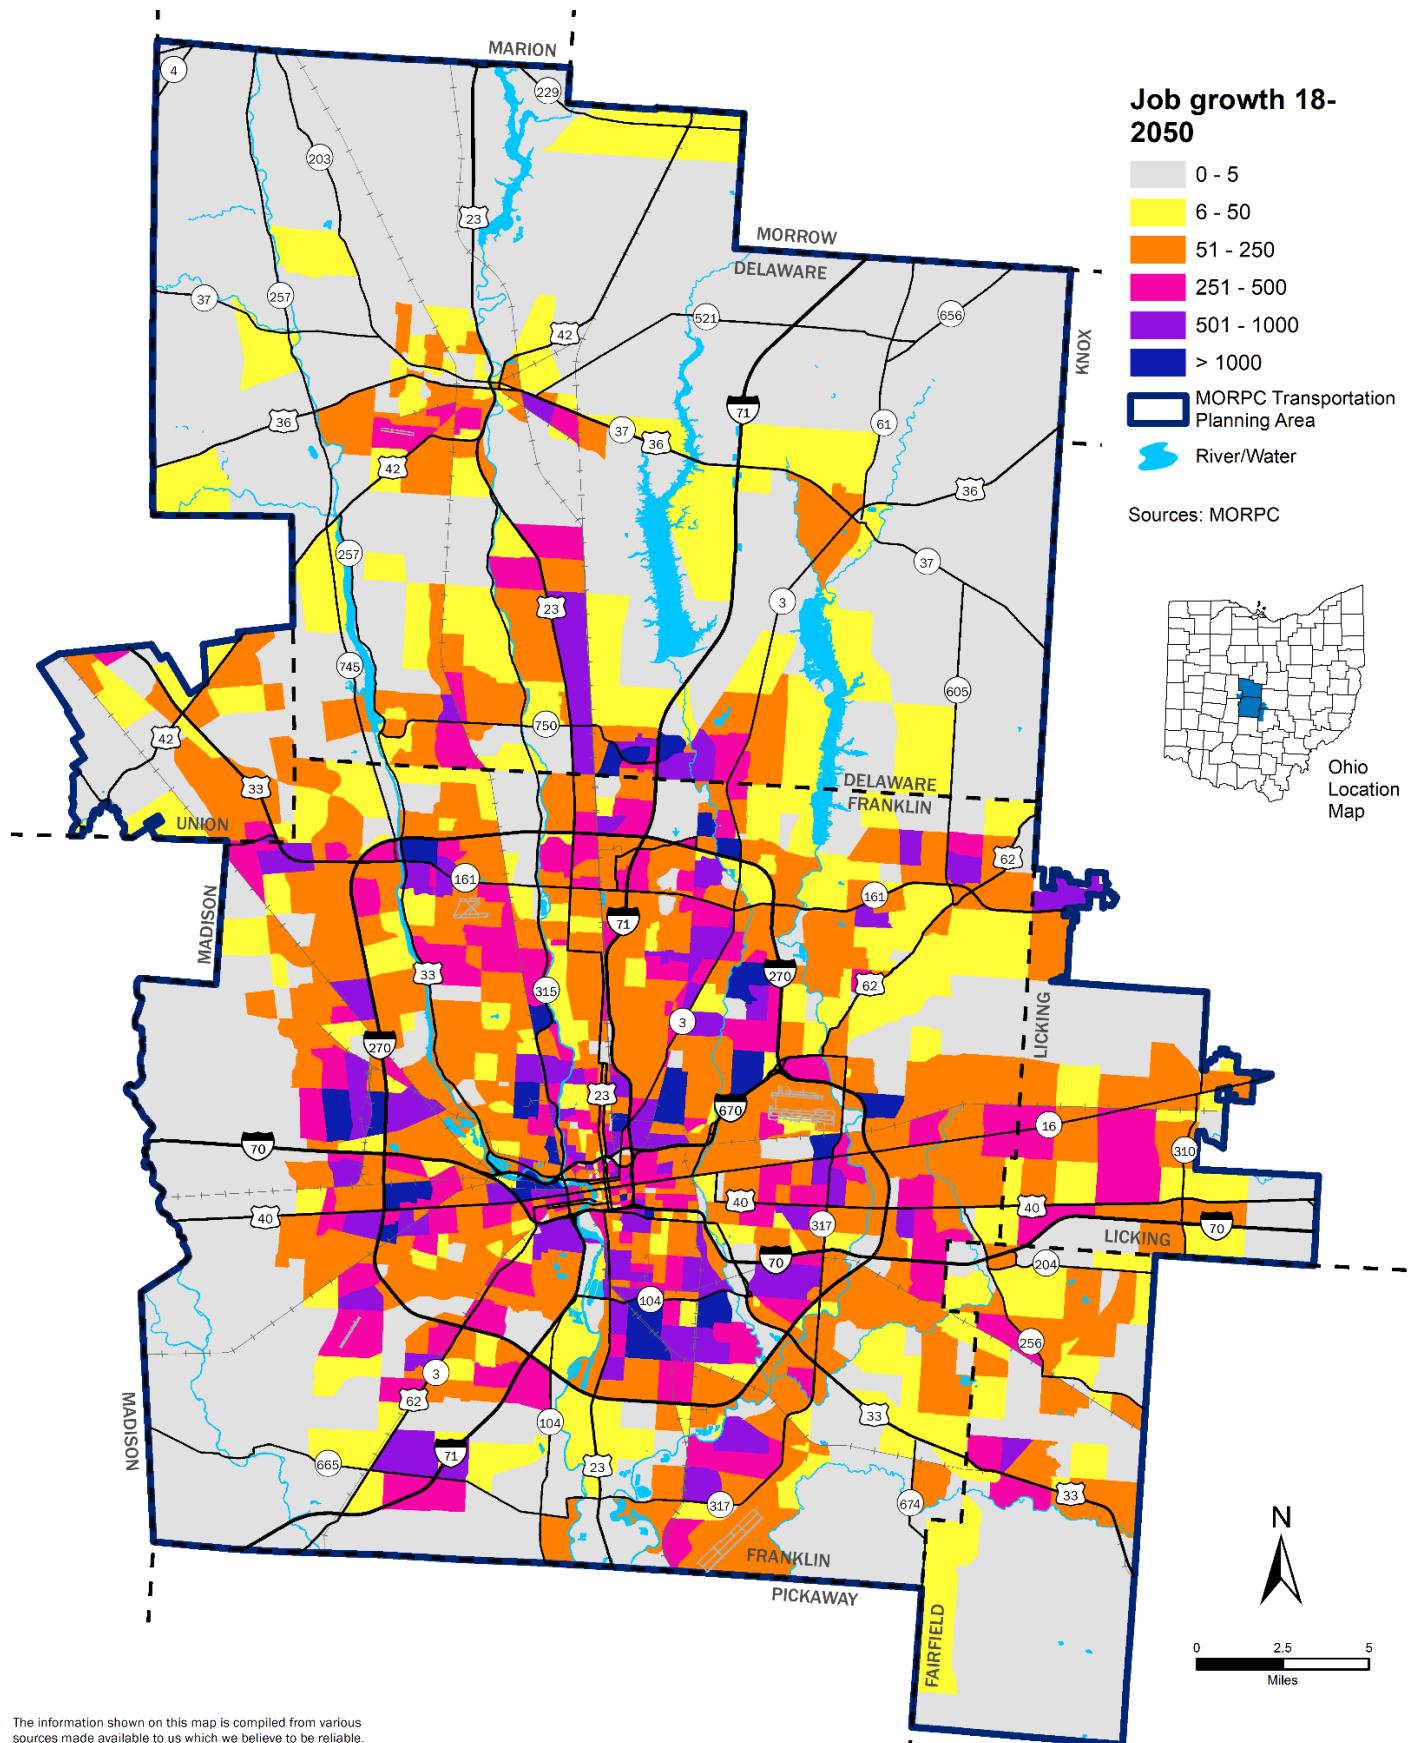

Figure 22. Population Growth by Traffic Analysis Zones

The information shown on this map is compiled from various sources made available to us which we believe to be reliable.
